Type.IsGenericTypeParameter Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current Type represents a type parameter in the definition of a generic type.

C#

```
public virtual bool IsGenericTypeParameter { get; }
```

Property Value

Boolean

`true` if the Type object represents a type parameter of a generic type definition; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Type.IsImport Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type has a ComImportAttribute attribute applied, indicating that it was imported from a COM type library.

```
C#
public bool IsImport { get; }
```

Property Value

Boolean

`true` if the Type has a ComImportAttribute; otherwise, `false`.

Remarks

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>.`

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsInterface Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is an interface; that is, not a class or a value type.

C#

```
public bool IsInterface { get; }
```

Property Value

Boolean

`true` if the Type is an interface; otherwise, `false`.

Examples

The following example creates an interface, checks for the interface type, and indicates whether a class has the `IsInterface` property set.

C#

```
using System;
// Declare an interface.
interface myIFace
{
}
class MyIsInterface
{
    public static void Main(string []args)
    {
        try
        {
            // Get the IsInterface attribute for myIFace.
            bool myBool1 = typeof(myIFace).IsInterface;
            //Display the IsInterface attribute for myIFace.
            Console.WriteLine("Is the specified type an interface? {0}.",
myBool1);
```

```
            // Get the attribute IsInterface for MyIsInterface.
            bool myBool2 = typeof(MyIsInterface).IsInterface;
            //Display the IsInterface attribute for MyIsInterface.
            Console.WriteLine("Is the specified type an interface? {0}.",
myBool2);
        }
        catch(Exception e)
        {
            Console.WriteLine("\nAn exception occurred: {0}.", e.Message);
        }
    }
}
/* The example produces the following output:

Is the specified type an interface? True.
Is the specified type an interface? False.
*/
```

Remarks

The ClassSemanticsMask distinguishes a type declaration as class, interface or value type.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

This property is read-only.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsLayoutSequential Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the fields of the current type are laid out sequentially, in the order that they were defined or emitted to the metadata.

C#

```
public bool IsLayoutSequential { get; }
```

Property Value

Boolean

`true` if the Attributes property of the current type includes SequentialLayout; otherwise, `false`.

Examples

The following example creates an instance of a class for which the LayoutKind.Sequential enumeration value in the StructLayoutAttribute class has been set, checks for the IsLayoutSequential property, and displays the result.

C#

```
using System;
using System.Reflection;
using System.ComponentModel;
using System.Runtime.InteropServices;
class MyTypeSequential1
{
}
[StructLayoutAttribute(LayoutKind.Sequential)]
class MyTypeSequential2
{
    public static void Main(string []args)
    {
        try
```

```
        {
            // Create an instance of myTypeSeq1.
            MyTypeSequential1 myObj1 = new MyTypeSequential1();
            Type myTypeObj1 = myObj1.GetType();
            // Check for and display the SequentialLayout attribute.
            Console.WriteLine("\nThe object myObj1 has IsLayoutSequential:
{0}.", myObj1.GetType().IsLayoutSequential);
            // Create an instance of 'myTypeSeq2' class.
            MyTypeSequential2 myObj2 = new MyTypeSequential2();
            Type myTypeObj2 = myObj2.GetType();
            // Check for and display the SequentialLayout attribute.
            Console.WriteLine("\nThe object myObj2 has IsLayoutSequential:
{0}.", myObj2.GetType().IsLayoutSequential);
        }
        catch(Exception e)
        {
            Console.WriteLine("\nAn exception occurred: {0}", e.Message);
        }
    }
}
```

Remarks

This property is provided as a convenience. Alternatively, you can use the TypeAttributes.LayoutMask enumeration value to select the type layout attributes, and then test whether TypeAttributes.SequentialLayout is set. The TypeAttributes.AutoLayout, TypeAttributes.ExplicitLayout, and TypeAttributes.SequentialLayout enumeration values indicate the way the fields of the type are laid out in memory.

For dynamic types, you can specify TypeAttributes.SequentialLayout when you create the type. In code, apply the StructLayoutAttribute attribute with the LayoutKind.Sequential enumeration value to the type, to specify that layout is sequential.

> ⓘ **Note**
>
> You cannot use the **GetCustomAttributes** method to determine whether the **StructLayoutAttribute** has been applied to a type.

For more information, see section 9.1.2 of the specification for the Common Language Infrastructure (CLI) documentation, "Partition II: Metadata Definition and Semantics".

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current

Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsMarshalByRef Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is marshaled by reference.

C#

```
public bool IsMarshalByRef { get; }
```

Property Value

Boolean

`true` if the Type is marshaled by reference; otherwise, `false`.

Examples

The following example demonstrates the IsContextful, `IsMarshalByRef`, and IsPrimitive properties of the Type class. It checks whether the given type can be hosted in the context, whether it can be marshaled by reference, and whether the type is a primitive data type.

C#

```
using System;
using System.Runtime.Remoting.Contexts;

public class ContextBoundClass: ContextBoundObject
{
    public string Value = "The Value property.";
}

public class Example
{
    public static void Main()
    {
         // Determine whether the types can be hosted in a Context.
         Console.WriteLine("The IsContextful property for the {0} type is
{1}.",
```

```
                            typeof(Example).Name,
typeof(Example).IsContextful);
         Console.WriteLine("The IsContextful property for the {0} type is
{1}.",
                            typeof(ContextBoundClass).Name,
typeof(ContextBoundClass).IsContextful);

         // Determine whether the types are marshalled by reference.
         Console.WriteLine("The IsMarshalByRef property of {0} is {1}.",
                            typeof(Example).Name,
typeof(Example).IsMarshalByRef);
         Console.WriteLine("The IsMarshalByRef property of {0} is {1}.",
                            typeof(ContextBoundClass).Name,
typeof(ContextBoundClass).IsMarshalByRef);

         // Determine whether the types are primitive datatypes.
         Console.WriteLine("{0} is a primitive data type: {1}.",
                            typeof(int).Name, typeof(int).IsPrimitive);
         Console.WriteLine("{0} is a primitive data type: {1}.",
                            typeof(string).Name, typeof(string).IsPrimitive);
    }
}
// The example displays the following output:
//    The IsContextful property for the Example type is False.
//    The IsContextful property for the ContextBoundClass type is True.
//    The IsMarshalByRef property of Example is False.
//    The IsMarshalByRef property of ContextBoundClass is True.
//    Int32 is a primitive data type: True.
//    String is a primitive data type: False.
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsNested Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the current Type object represents a type whose definition is nested inside the definition of another type.

C#

```
public bool IsNested { get; }
```

Property Value

Boolean

`true` if the Type is nested inside another type; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

C#

```
using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}

    protected internal class ProtectedInternalClass
```

```
    {}

    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
```

```
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

The IsNested property returns `true` for all nested types, regardless of visibility. To test for nesting and visibility at the same time, use the related properties IsNestedAssembly,

IsNestedFamily, IsNestedFamANDAssem, IsNestedFamORAssem, IsNestedPrivate, or IsNestedPublic.

> **Note**
>
> The **VisibilityMask** enumeration member selects the visibility attributes for a type.

Applies to

Type.IsNestedAssembly Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is nested and visible only within its own assembly.

C#

```
public bool IsNestedAssembly { get; }
```

Property Value

Boolean

`true` if the Type is nested and visible only within its own assembly; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

C#

```
using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}

    protected internal class ProtectedInternalClass
```

```
    {}

    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
```

```
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

If the current Type represents a type parameter of a generic type, this property always returns `false`.

TypeAttributes.VisibilityMask selects the visibility attributes.

Applies to

Type.IsNestedFamANDAssem Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is nested and visible only to classes that belong to both its own family and its own assembly.

```
C#

public bool IsNestedFamANDAssem { get; }
```

Property Value

Boolean

`true` if the Type is nested and visible only to classes that belong to both its own family and its own assembly; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

```
C#

using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}
```

```
    protected internal class ProtectedInternalClass
    {}

    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
```

```
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

If the current Type represents a type parameter of a generic type, this property always returns `false`.

TypeAttributes.VisibilityMask selects the visibility attributes.

> **Note**
>
> The C# and Visual Basic languages do not include semantics that allow you to define a nested type that is visible only to protected types in its own assembly. `protected internal` visibility in C# and `Protected Friend` visibility in Visual Basic define a nested type that is visible both to protected types and to types in the same assembly.

A Type object's family is defined as all objects of the same Type and of its subtypes.

Type.IsNestedFamily Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is nested and visible only within its own family.

C#

```
public bool IsNestedFamily { get; }
```

Property Value

Boolean

`true` if the Type is nested and visible only within its own family; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

C#

```
using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}

    protected internal class ProtectedInternalClass
    {}
```

```
    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
```

```
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

If the current Type represents a type parameter of a generic type, this property always returns `false`.

TypeAttributes.VisibilityMask selects the visibility attributes.

A Type object's family is defined as all objects of the exact same Type and of its subtypes.

Type.IsNestedFamORAssem Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is nested and visible only to classes that belong to either its own family or to its own assembly.

C#

```
public bool IsNestedFamORAssem { get; }
```

Property Value

Boolean

`true` if the Type is nested and visible only to classes that belong to its own family or to its own assembly; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

C#

```
using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}
```

```
    protected internal class ProtectedInternalClass
    {}

    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
```

```
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

If the visibility of a type is `protected internal` in C# or `Protected Friend` in Visual Basic, the IsNestedFamORAssem property returns `true`.

If the current Type represents a type parameter of a generic type, this property always returns `false`.

TypeAttributes.VisibilityMask selects the visibility attributes.

A Type object's family is defined as all objects of the exact same Type and of its subtypes.

Type.IsNestedPrivate Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is nested and declared private.

C#

```
public bool IsNestedPrivate { get; }
```

Property Value

Boolean

`true` if the Type is nested and declared private; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

C#

```
using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}

    protected internal class ProtectedInternalClass
    {}
```

```
    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
```

```
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

If the current Type represents a type parameter of a generic type, this property always returns `false`.

TypeAttributes.VisibilityMask selects the visibility attributes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsNestedPublic Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether a class is nested and declared public.

C#

```
public bool IsNestedPublic { get; }
```

Property Value

Boolean

`true` if the class is nested and declared public; otherwise, `false`.

Examples

The following example creates an outer class with a number of nested classes that have various types of visibility. It then retrieves the value of a number of visibility-related Type properties for the parent type and each of its nested types.

C#

```
using System;

// Create a class with a number of nested classes.
public class OuterClass
{
    private class PrivateClass
    {}

    protected class ProtectedClass
    {}

    internal class InternalClass
    {}

    protected internal class ProtectedInternalClass
    {}
```

```
    public class PublicClass
    {}

    public static void Main()
    {
        // Create an array of Type objects for all the classes.
        Type[] types = { typeof(OuterClass),
                         typeof(OuterClass.PublicClass),
                         typeof(OuterClass.PrivateClass),
                         typeof(OuterClass.ProtectedClass),
                         typeof(OuterClass.InternalClass),
                         typeof(OuterClass.ProtectedInternalClass) };
        // Display the property values of each nested class.
        foreach (var type in types) {
           Console.WriteLine("\n{0} property values:", type.Name);
           Console.WriteLine("   Public Class: {0}", type.IsPublic);
           Console.WriteLine("   Not a Public Class: {0}",
type.IsNotPublic);
           Console.WriteLine("   Nested Class: {0}", type.IsNested);
           Console.WriteLine("   Nested Private Class: {0}",
type.IsNestedPrivate);
           Console.WriteLine("   Nested Internal Class: {0}",
type.IsNestedAssembly);
           Console.WriteLine("   Nested Protected Class: {0}",
type.IsNestedFamily);
           Console.WriteLine("   Nested Family Or Assembly Class: {0}",
type.IsNestedFamORAssem);
           Console.WriteLine("   Nested Family And Assembly Class: {0}",
type.IsNestedFamANDAssem);
           Console.WriteLine("   Nested Public Class: {0}",
type.IsNestedPublic);
        }
    }
}
// The example displays the following output:
//    OuterClass property values:
//       Public Class: True
//       Not a Public Class: False
//       Nested Class: False
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    PublicClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
```

```
//       Nested Family And Assembly Class: False
//       Nested Public Class: True
//
//    PrivateClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: True
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: True
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    InternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: True
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: False
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
//
//    ProtectedInternalClass property values:
//       Public Class: False
//       Not a Public Class: False
//       Nested Class: True
//       Nested Private Class: False
//       Nested Internal Class: False
//       Nested Protected Class: False
//       Nested Family Or Assembly Class: True
//       Nested Family And Assembly Class: False
//       Nested Public Class: False
```

Remarks

If the current Type represents a type parameter of a generic type, this property always returns `false`.

TypeAttributes.VisibilityMask selects the visibility attributes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsNotPublic Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is not declared public.

C#

```
public bool IsNotPublic { get; }
```

Property Value

Boolean

`true` if the Type is not declared public and is not a nested type; otherwise, `false`.

Examples

This example uses the `IsNotPublic` property to get the visibility of the type.

C#

```
using System;
using System.IO;
using System.Reflection;

class Example
{
    public static void Main()
    {
        // Get the Type and MemberInfo.
        Type t = Type.GetType("System.IO.File");
        MemberInfo[] members = t.GetMembers();
        // Get and display the DeclaringType method.
        Console.WriteLine("\nThere are {0} members in {1}.",
                          members.Length, t.FullName);
        Console.WriteLine("Is {0} non-public? {1}",
                          t.FullName, t.IsNotPublic);
    }
}
// The example displays output like the following:
```

```
//       There are 60 members in System.IO.File.
//       Is System.IO.File non-public? False
```

The following code example demonstrates why you cannot use `IsPublic` and `IsNotPublic` for nested classes.

```C#
public class A
{
    public class B { }
    private class C { }
}
```

For nested classes, ignore the results of `IsPublic` and `IsNotPublic` and pay attention only to the results of `IsNestedPublic` and `IsNestedPrivate`. The reflection output for this code fragment would be as follows:

Expand table

Class	IsNotPublic	IsPublic	IsNestedPublic	IsNestedPrivate
A	FALSE	TRUE	FALSE	FALSE
B	FALSE	FALSE	TRUE	FALSE
C	FALSE	FALSE	FALSE	TRUE

Remarks

Do not use this property with nested types; use the IsNestedPublic property instead.

If the current Type represents a type parameter of a generic type, this property returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsPointer Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is a pointer.

C#

```
public bool IsPointer { get; }
```

Property Value

Boolean

`true` if the Type is a pointer; otherwise, `false`.

Examples

The following example shows a use of the `IsPointer` property.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegator : TypeDelegator
{
    public string myElementType = null;
    private Type myType = null ;
    public MyTypeDelegator(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override Type.HasElementTypeImpl().
    protected override bool HasElementTypeImpl()
    {
        // Determine whether the type is an array.
        if(myType.IsArray)
        {
            myElementType = "array";
            return true;
        }
```

```
        // Determine whether the type is a reference.
        if(myType.IsByRef)
        {
            myElementType = "reference";
            return true;
        }
        // Determine whether the type is a pointer.
        if(myType.IsPointer)
        {
            myElementType = "pointer";
            return true;
        }
        // Return false if the type is not a reference, array, or pointer
type.
        return false;
    }
}
public class Type_HasElementTypeImpl
{
    public static void Main()
    {
        try
        {
            int myInt = 0 ;
            int[] myArray = new int[5];
            MyTypeDelegator myType = new MyTypeDelegator(myArray.GetType());
            // Determine whether myType is an array, pointer, reference
type.
            Console.WriteLine("\nDetermine whether a variable is an array,
pointer, or reference type.\n");
            if( myType.HasElementType)
                Console.WriteLine("The type of myArray is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myArray is not an array, pointer, or
reference type.");
            myType = new MyTypeDelegator(myInt.GetType());
            // Determine whether myType is an array, pointer, reference
type.
            if( myType.HasElementType)
                Console.WriteLine("The type of myInt is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myInt is not an array, pointer, or
reference type.");
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message);
        }
    }
}
```

Remarks

If the current Type represents a generic type, or a type parameter in the definition of a generic type or generic method, this property always returns `false`.

This property is read-only.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.IsPrimitive Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is one of the primitive types.

C#

```
public bool IsPrimitive { get; }
```

Property Value

Boolean

`true` if the Type is one of the primitive types; otherwise, `false`.

Examples

The following example demonstrates the IsContextful, IsMarshalByRef, and `IsPrimitive` properties of the Type class. It checks whether the given type can be hosted in the context, whether it can be marshaled by reference, and whether the type is a primitive data type.

C#

```
using System;
using System.Runtime.Remoting.Contexts;

public class ContextBoundClass: ContextBoundObject
{
    public string Value = "The Value property.";
}

public class Example
{
    public static void Main()
    {
         // Determine whether the types can be hosted in a Context.
         Console.WriteLine("The IsContextful property for the {0} type is
{1}.",
```

```
                            typeof(Example).Name,
typeof(Example).IsContextful);
         Console.WriteLine("The IsContextful property for the {0} type is
{1}.",
                            typeof(ContextBoundClass).Name,
typeof(ContextBoundClass).IsContextful);

         // Determine whether the types are marshalled by reference.
         Console.WriteLine("The IsMarshalByRef property of {0} is {1}.",
                            typeof(Example).Name,
typeof(Example).IsMarshalByRef);
         Console.WriteLine("The IsMarshalByRef property of {0} is {1}.",
                            typeof(ContextBoundClass).Name,
typeof(ContextBoundClass).IsMarshalByRef);

         // Determine whether the types are primitive datatypes.
         Console.WriteLine("{0} is a primitive data type: {1}.",
                            typeof(int).Name, typeof(int).IsPrimitive);
         Console.WriteLine("{0} is a primitive data type: {1}.",
                            typeof(string).Name, typeof(string).IsPrimitive);
    }
}
// The example displays the following output:
//    The IsContextful property for the Example type is False.
//    The IsContextful property for the ContextBoundClass type is True.
//    The IsMarshalByRef property of Example is False.
//    The IsMarshalByRef property of ContextBoundClass is True.
//    Int32 is a primitive data type: True.
//    String is a primitive data type: False.
```

Remarks

The primitive types are Boolean, Byte, SByte, Int16, UInt16, Int32, UInt32, Int64, UInt64, IntPtr, UIntPtr, Char, Double, and Single.

If the current Type represents a generic type, or a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsPublic Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is declared public.

C#

```
public bool IsPublic { get; }
```

Property Value

Boolean

`true` if the Type is declared public and is not a nested type; otherwise, `false`.

Examples

The following example creates an instance of `MyTestClass`, checks for the `IsPublic` property, and displays the result.

C#

```
using System;

public class TestClass
{
}

public class Example
{
   public static void Main()
   {
      TestClass testClassInstance = new TestClass();
      // Get the type of myTestClassInstance.
      Type   testType = testClassInstance.GetType();
      // Get the IsPublic property of testClassInstance.
      bool isPublic = testType.IsPublic;
      Console.WriteLine("Is {0} public? {1}", testType.FullName, isPublic);
   }
```

```
}
// The example displays the following output:
//        Is TestClass public? True
```

For nested classes, ignore the results of `IsPublic` and `IsNotPublic` and pay attention only to the results of IsNestedPublic and IsNestedPrivate.

Remarks

Do not use with nested types; use IsNestedPublic instead.

If the current Type represents a type parameter of a generic type, this property returns `true`.

TypeAttributes.VisibilityMask selects the visibility attributes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsSealed Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is declared sealed.

C#

```
public bool IsSealed { get; }
```

Property Value

Boolean

`true` if the Type is declared sealed; otherwise, `false`.

Examples

The following example creates an instance of a `sealed` class, checks for the `IsSealed` property, and displays the result.

C#

```
using System;

 public class Example
 {
     // Declare InnerClass as sealed.
     sealed public class InnerClass
     {
     }

     public static void Main()
     {
          InnerClass inner = new InnerClass();
          // Get the type of InnerClass.
          Type innerType = inner.GetType();
          // Get the IsSealed property of  innerClass.
          bool isSealed = innerType.IsSealed;
          Console.WriteLine("{0} is sealed: {1}.", innerType.FullName,
```

```
isSealed);
     }
}
// The example displays the following output:
//        Example+InnerClass is sealed: True.
```

Remarks

If the current Type represents a type parameter of a generic type, this property always returns `true`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsSecurityCritical Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current type is security-critical or security-safe-critical at the current trust level, and therefore can perform critical operations.

```
C#
public virtual bool IsSecurityCritical { get; }
```

Property Value

Boolean

`true` if the current type is security-critical or security-safe-critical at the current trust level; `false` if it is transparent.

Remarks

The IsSecurityCritical, IsSecuritySafeCritical, and IsSecurityTransparent properties report the transparency level of the type at its current trust level, as determined by the common language runtime (CLR). The combinations of these properties are shown in the following table:

Expand table

Security level	IsSecurityCritical	IsSecuritySafeCritical	IsSecurityTransparent
Critical	`true`	`false`	`false`
Safe critical	`true`	`true`	`false`
Transparent	`false`	`false`	`true`

Using these properties is much simpler than examining the security annotations of an assembly and its types, checking the current trust level, and attempting to duplicate the

runtime's rules.

> **Important**
>
> For partial-trust assemblies, the value of this property depends on the current trust level of the assembly. If the assembly is loaded into a partially trusted application domain (for example, into a sandboxed application domain), then the runtime ignores the security annotations of the assembly. The assembly and all its types are treated as transparent. The runtime pays attention to the security annotations of a partial-trust assembly only when that assembly is loaded into a fully trusted application domain (for example, into the default application domain of a desktop application). By contrast, a trusted assembly (that is, a strong-named assembly that is installed in the global assembly cache) is always loaded with full trust regardless of the trust level of the application domain, so its current trust level is always fully trusted. You can determine the current trust levels of assemblies and application domains by using the **Assembly.IsFullyTrusted** and **AppDomain.IsFullyTrusted** properties.

For more information about reflection and transparency, see Security Considerations for Reflection. For information about transparency, see Security Changes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsSecuritySafeCritical Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current type is security-safe-critical at the current trust level; that is, whether it can perform critical operations and can be accessed by transparent code.

C#

```
public virtual bool IsSecuritySafeCritical { get; }
```

Property Value

Boolean

`true` if the current type is security-safe-critical at the current trust level; `false` if it is security-critical or transparent.

Remarks

The IsSecurityCritical, IsSecuritySafeCritical, and IsSecurityTransparent properties report the transparency level of the type at its current trust level, as determined by the common language runtime (CLR). The combinations of these properties are shown in the following table:

Expand table

Security level	IsSecurityCritical	IsSecuritySafeCritical	IsSecurityTransparent
Critical	`true`	`false`	`false`
Safe critical	`true`	`true`	`false`
Transparent	`false`	`false`	`true`

Using these properties is much simpler than examining the security annotations of an assembly and its types, checking the current trust level, and attempting to duplicate the runtime's rules.

> **Important**
>
> For partial-trust assemblies, the value of this property depends on the current trust level of the assembly. If the assembly is loaded into a partially trusted application domain (for example, into a sandboxed application domain), then the runtime ignores the security annotations of the assembly. The assembly and all its types are treated as transparent. The runtime pays attention to the security annotations of a partial-trust assembly only when that assembly is loaded into a fully trusted application domain (for example, into the default application domain of a desktop application). By contrast, a trusted assembly (that is, a strong-named assembly that is installed in the global assembly cache) is always loaded with full trust regardless of the trust level of the application domain, so its current trust level is always fully trusted. You can determine the current trust levels of assemblies and application domains by using the **Assembly.IsFullyTrusted** and **AppDomain.IsFullyTrusted** properties.

For more information about reflection and transparency, see Security Considerations for Reflection. For information about transparency, see Security Changes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsSecurityTransparent Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current type is transparent at the current trust level, and therefore cannot perform critical operations.

```
C#
public virtual bool IsSecurityTransparent { get; }
```

Property Value

Boolean

`true` if the type is security-transparent at the current trust level; otherwise, `false`.

Remarks

If this property returns `true`, the IsSecurityCritical and IsSecuritySafeCritical properties return `false`.

The IsSecurityCritical, IsSecuritySafeCritical, and IsSecurityTransparent properties report the transparency level of the type at its current trust level, as determined by the common language runtime (CLR). Using these properties is much simpler than examining the security annotations of an assembly and its types, checking the current trust level, and attempting to duplicate the runtime's rules.

> **Important**
>
> For partial-trust assemblies, the value of this property depends on the current trust level of the assembly. If the assembly is loaded into a partially trusted application domain (for example, into a sandboxed application domain), then the runtime ignores the security annotations of the assembly. The assembly and all its types are treated as transparent. The runtime pays attention to the security annotations of a partial-trust assembly only when that assembly is loaded into a fully trusted

application domain (for example, into the default application domain of a desktop application). By contrast, a trusted assembly (that is, a strong-named assembly that is installed in the global assembly cache) is always loaded with full trust regardless of the trust level of the application domain, so its current trust level is always fully trusted. You can determine the current trust levels of assemblies and application domains by using the **Assembly.IsFullyTrusted** and **AppDomain.IsFullyTrusted** properties.

For more information about reflection and transparency, see Security Considerations for Reflection. For information about transparency, see Security Changes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsSerializable Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Formatter-based serialization is obsolete and should not be used.

Gets a value indicating whether the Type is binary serializable.

C#

```
[System.Obsolete("Formatter-based serialization is obsolete and should not be used.", DiagnosticId="SYSLIB0050", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public virtual bool IsSerializable { get; }
```

Property Value

Boolean

`true` if the Type is binary serializable; otherwise, `false`.

Attributes ObsoleteAttribute

Examples

The following example creates an instance of `MyTestClass` class, sets the [Serializable] attribute, and checks the `IsSerializable` property for `true` or `false`.

C#

```
using System;
namespace SystemType
{
    public class MyClass
```

```
    {
        // Declare a public class with the [Serializable] attribute.
        [Serializable] public class MyTestClass
        {
        }
        public static void Main(string []args)
        {
            try
            {
                bool myBool = false;
                MyTestClass myTestClassInstance = new MyTestClass();
                // Get the type of myTestClassInstance.
                Type myType = myTestClassInstance.GetType();
                // Get the IsSerializable property of myTestClassInstance.
                myBool = myType.IsSerializable;
                Console.WriteLine("\nIs {0} serializable? {1}.",
myType.FullName, myBool.ToString());
            }
            catch (Exception e)
            {
                Console.WriteLine("\nAn exception occurred: {0}",
e.Message);
            }
        }
    }
}
```

Remarks

Types that are defined in the .NET Standard are not marked with SerializableAttribute. Instead, each .NET implementation determines whether a type is binary serializable. At run time, you can use the IsSerializable property to determine whether that implementation supports binary serialization of an instance of the type. For more information and an example, see How to determine if a .NET Standard object is serializable.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsSignatureType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the type is a signature type.

C#

```
public virtual bool IsSignatureType { get; }
```

Property Value

Boolean

`true` if the Type is a signature type; otherwise, `false`.

Remarks

A signature type is a restricted type that can be passed to the GetMethod method but does not support most of the other reflection functionality. For example, you can obtain the signature type instance corresponding to the generic method parameter by calling the MakeGenericMethodParameter method.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Type.IsSpecialName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the type has a name that requires special handling.

C#

```
public bool IsSpecialName { get; }
```

Property Value

Boolean

`true` if the type has a name that requires special handling; otherwise, `false`.

Remarks

Names that begin with or contain an underscore character (_), property accessors, and operator overloading methods are examples of types that might require special treatment by some compilers.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsSZArray Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the type is an array type that can represent only a single-dimensional array with a zero lower bound.

```
C#
public virtual bool IsSZArray { get; }
```

Property Value

Boolean

`true` if the current Type is an array type that can represent only a single-dimensional array with a zero lower bound; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Type.IsTypeDefinition Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the type is a type definition.

C#

```
public virtual bool IsTypeDefinition { get; }
```

Property Value

Boolean

`true` if the current Type is a type definition; otherwise, `false`.

Remarks

A Type instance is a type definition if it represents the type directly defined in assembly, in contrast to types that are constructed on demand based on other types. For example, a primitive type, class, structure, or generic type definition is a type definition, but an array, reference, pointer, or instantiated generic type isn't.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Type.IsUnicodeClass Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the string format attribute `UnicodeClass` is selected for the Type.

```
C#
public bool IsUnicodeClass { get; }
```

Property Value

Boolean

`true` if the string format attribute `UnicodeClass` is selected for the Type; otherwise, `false`.

Remarks

The StringFormatMask is used to select the string format attributes. The string format attributes enhance interoperability by defining how strings should be interpreted.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsUnmanagedFunctionPointer Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the current Type is an unmanaged function pointer.

C#

```
public virtual bool IsUnmanagedFunctionPointer { get; }
```

Property Value

Boolean

`true` if the current Type is an unmanaged function pointer; otherwise, `false`.

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Type.IsValueType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type is a value type.

C#

```
public bool IsValueType { get; }
```

Property Value

Boolean

`true` if the Type is a value type; otherwise, `false`.

Examples

The following example creates a variable of type `MyEnum`, checks for the `IsValueType` property, and displays the result.

C#

```
using System;

// Declare an enum type.
enum NumEnum { One, Two }

public class Example
{

    public static void Main(string []args)
    {
        bool flag = false;
        NumEnum testEnum = NumEnum.One;
        // Get the type of testEnum.
        Type t = testEnum.GetType();
        // Get the IsValueType property of the testEnum variable.
        flag = t.IsValueType;
        Console.WriteLine("{0} is a value type: {1}", t.FullName, flag);
```

```
    }
}
// The example displays the following output:
//        NumEnum is a value type: True
```

Remarks

Value types are types that are represented as sequences of bits; value types are not classes or interfaces. Value types are referred to as "structs" in some programming languages. Enums are a special case of value types.

This property returns `false` for the ValueType class, because ValueType is not a value type itself. It is the base class for all value types, and therefore any value type can be assigned to it. This would not be possible if ValueType itself was a value type. Value types are boxed when they are assigned to a field of type ValueType.

This property returns `true` for enumerations, but not for the Enum type itself. For an example that demonstrates this behavior, see IsEnum.

This property is read-only.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsVariableBoundArray Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the type is an array type that can represent a multi-dimensional array or an array with an arbitrary lower bound.

```
C#
public virtual bool IsVariableBoundArray { get; }
```

Property Value

Boolean

`true` if the current Type is an array type that can represent a multi-dimensional array or an array with an arbitrary lower bound; otherwise, `false`.

Remarks

If the value of this property is `true` for an array type, it can be used to create single-dimensional or multi-dimensional array instances with arbitrary lower bounds. Otherwise, the array type can only be used to create instances of single-dimensional arrays with a zero lower bound.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Type.IsVisible Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value indicating whether the Type can be accessed by code outside the assembly.

C#

```
public bool IsVisible { get; }
```

Property Value

Boolean

`true` if the current Type is a public type or a public nested type such that all the enclosing types are public; otherwise, `false`.

Examples

The following code example tests two classes, only one of which is visible outside the assembly.

C#

```
using System;

internal class InternalOnly
{
    public class Nested {}
}

public class Example
{
    public class Nested {}

    public static void Main()
    {
        Type t = typeof(InternalOnly.Nested);
        Console.WriteLine(
            "Is the {0} class visible outside the assembly? {1}",
```

```
            t.FullName,
            t.IsVisible
        );

        t = typeof(Example.Nested);
        Console.WriteLine(
            "Is the {0} class visible outside the assembly? {1}",
            t.FullName,
            t.IsVisible
        );
    }
}

/* This example produces the following output:

Is the InternalOnly+Nested class visible outside the assembly? False
Is the Example+Nested class visible outside the assembly? True
 */
```

Remarks

Use this property to determine whether a type is part of the public interface of a component assembly.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.MemberType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a MemberTypes value indicating that this member is a type or a nested type.

```
C#

public override System.Reflection.MemberTypes MemberType { get; }
```

Property Value

MemberTypes

A MemberTypes value indicating that this member is a type or a nested type.

Examples

The following code example shows the `MemberType` field as a parameter to the `GetMember` method:

```
C#

MemberInfo[] others = t.GetMember(mi.Name, mi.MemberType,
BindingFlags.Public |
BindingFlags.Static | BindingFlags.NonPublic | BindingFlags.Instance);
```

Remarks

This property overrides MemberInfo.MemberType. Therefore, when you examine a set of MemberInfo objects - for example, the array returned by GetMembers - the MemberType property returns MemberTypes.NestedType when a given member is a nested type.

If the current Type represents a constructed generic type, this property applies to the generic type definition from which the type was constructed. For example, if the current

Type represents `MyGenericType<int>` (`MyGenericType(Of Integer)` in Visual Basic), the value of this property is determined by `MyGenericType<T>`.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property always returns MemberTypes.TypeInfo.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.Module Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the module (the DLL) in which the current Type is defined.

C#

```
public abstract System.Reflection.Module Module { get; }
```

Property Value

Module

The module in which the current Type is defined.

Examples

This following example demonstrates a use of the Namespace and `Module` properties and the ToString method of Type.

C#

```
using System;

namespace MyNamespace
{
    class MyClass
    {
    }
}

public class Example
{
    public static void Main()
    {
         Type myType = typeof(MyNamespace.MyClass);
         Console.WriteLine("Displaying information about {0}:", myType);
         // Get the namespace of the myClass class.
         Console.WriteLine("   Namespace: {0}.", myType.Namespace);
```

```
            // Get the name of the module.
            Console.WriteLine("   Module: {0}.", myType.Module);
            // Get the fully qualified type name.
            Console.WriteLine("   Fully qualified name: {0}.",
myType.ToString());
        }
    }
// The example displays the following output:
//    Displaying information about MyNamespace.MyClass:
//       Namespace: MyNamespace.
//       Module: type_tostring.exe.
//       Fully qualified name: MyNamespace.MyClass.
```

Remarks

If the current Type represents a constructed generic type, this property returns the module in which the generic type definition was defined. For example, if you create an instance of `MyGenericStack<int>`, the Module property for the constructed type returns the module in which `MyGenericStack<T>` is defined.

Similarly, if the current Type represents a generic parameter `T`, this property returns the assembly that contains the generic type that defines `T`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.Namespace Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the namespace of the Type.

C#

```
public abstract string? Namespace { get; }
```

Property Value

String

The namespace of the Type; `null` if the current instance has no namespace or represents a generic parameter.

Examples

This following example demonstrates a use of the `Namespace` and Module properties and the ToString method of Type.

C#

```
using System;

namespace MyNamespace
{
    class MyClass
    {
    }
}

public class Example
{
    public static void Main()
    {
         Type myType = typeof(MyNamespace.MyClass);
         Console.WriteLine("Displaying information about {0}:", myType);
         // Get the namespace of the myClass class.
```

```
            Console.WriteLine("   Namespace: {0}.", myType.Namespace);
            // Get the name of the module.
            Console.WriteLine("   Module: {0}.", myType.Module);
            // Get the fully qualified type name.
            Console.WriteLine("   Fully qualified name: {0}.",
myType.ToString());
        }
}
// The example displays the following output:
//    Displaying information about MyNamespace.MyClass:
//       Namespace: MyNamespace.
//       Module: type_tostring.exe.
//       Fully qualified name: MyNamespace.MyClass.
```

Remarks

A namespace is a logical design-time naming convenience, used mainly to define scope in an application and organize classes and other types in a single hierarchical structure. From the viewpoint of the runtime, there are no namespaces.

If the current Type represents a constructed generic type, this property returns the namespace that contains the generic type definition. Similarly, if the current Type represents a generic parameter `T`, this property returns the namespace that contains the generic type definition that defines `T`.

If the current Type object represents a generic parameter and a generic type definition is not available, such as for a signature type returned by MakeGenericMethodParameter, this property returns `null`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.ReflectedType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the class object that was used to obtain this member.

C#

```
public override Type? ReflectedType { get; }
```

Property Value

Type

The `Type` object through which this Type object was obtained.

Examples

This example displays the reflected type of a nested class.

C#

```
using System;
using System.Reflection;

public abstract class MyClassA
{

    public abstract class MyClassB
    {
    }

    public static void Main(string[] args)
    {
        Console.WriteLine("Reflected type of MyClassB is {0}",
            typeof(MyClassB).ReflectedType); //outputs MyClassA, the
enclosing class
    }
}
```

Remarks

For Type objects, the value of this property is always the same as the value of the DeclaringType property.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.StructLayoutAttribute Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a StructLayoutAttribute that describes the layout of the current type.

C#

```
public virtual System.Runtime.InteropServices.StructLayoutAttribute?
StructLayoutAttribute { get; }
```

Property Value

StructLayoutAttribute

Gets a StructLayoutAttribute that describes the gross layout features of the current type.

Exceptions

NotSupportedException

The invoked method is not supported in the base class.

Examples

The following code example first defines a class, a structure, and a structure with special layout attributes (the structures are nested within the class). The example then uses the StructLayoutAttribute property to obtain a StructLayoutAttribute for each type, and displays the properties of the attributes.

C#

```
using System;
using System.Runtime.InteropServices;

public class Example
{
    public static void Main()
    {
```

```
        DisplayLayoutAttribute(typeof(Example).StructLayoutAttribute);
        DisplayLayoutAttribute(typeof(Test1).StructLayoutAttribute);
        DisplayLayoutAttribute(typeof(Test2).StructLayoutAttribute);
    }

    private static void DisplayLayoutAttribute(StructLayoutAttribute sla)
    {
        Console.WriteLine("\r\nCharSet: "+sla.CharSet.ToString()+"\r\n
Pack: "+sla.Pack.ToString()+"\r\n   Size: "+sla.Size.ToString()+"\r\n
Value: "+sla.Value.ToString());
    }
    public struct Test1
    {
        public byte B1;
        public short S;
        public byte B2;
    }
    [StructLayout(LayoutKind.Explicit, Pack=1)] public struct Test2
    {
        [FieldOffset(0)] public byte B1;
        [FieldOffset(1)] public short S;
        [FieldOffset(3)] public byte B2;
    }
}
```

Remarks

StructLayoutAttribute is not returned by the GetCustomAttributes method. Instead, use this property to get it.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.TypeHandle Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the handle for the current Type.

C#

```
public virtual RuntimeTypeHandle TypeHandle { get; }
```

Property Value

RuntimeTypeHandle

The handle for the current Type.

Exceptions

NotSupportedException

The .NET Compact Framework does not currently support this property.

Examples

The following example returns the handle of the corresponding type and passes the handle to a method that gets the type from the handle and displays it.

C#

```
using System;
using System.Reflection;
class MyClass
{
    public int myField = 10;
}

class Type_TypeHandle
{
    public static void Main()
    {
```

```
        try
        {
            MyClass myClass = new MyClass();

            // Get the type of MyClass.
            Type myClassType = myClass.GetType();

            // Get the runtime handle of MyClass.
            RuntimeTypeHandle myClassHandle = myClassType.TypeHandle;

            DisplayTypeHandle(myClassHandle);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: {0}", e.Message );
        }
    }

    public static void DisplayTypeHandle(RuntimeTypeHandle myTypeHandle)
    {
        // Get the type from the handle.
        Type myType = Type.GetTypeFromHandle(myTypeHandle);
        // Display the type.
        Console.WriteLine("\nDisplaying the type from the handle:\n");
        Console.WriteLine("The type is {0}.", myType.ToString());
    }
}
```

Remarks

`TypeHandle` encapsulates a pointer to an internal data structure that represents the type. This handle is unique during the process lifetime. The handle is valid only in the application domain in which it was obtained.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.TypeInitializer Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the initializer for the type.

C#

```
public System.Reflection.ConstructorInfo? TypeInitializer { get; }
```

Property Value

ConstructorInfo

An object that contains the name of the class constructor for the Type.

Remarks

Class initializers are also available through the FindMembers method, or through overloads of the GetMember, GetMembers, GetConstructor, and GetConstructors methods that take BindingFlags as a parameter.

If the current Type represents a type parameter in the definition of a generic type or generic method, this property returns `null`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.UnderlyingSystemType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates the type provided by the common language runtime that represents this type.

C#

```
public abstract Type UnderlyingSystemType { get; }
```

Property Value

Type

The underlying system type for the Type.

Implements

UnderlyingSystemType

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if the underlying system type of the current Type is the same as the underlying system type of the specified Object or Type.

Overloads

Expand table

Equals(Type)	Determines if the underlying system type of the current Type is the same as the underlying system type of the specified Type.
Equals(Object)	Determines if the underlying system type of the current Type object is the same as the underlying system type of the specified Object.

Equals(Type)

Determines if the underlying system type of the current Type is the same as the underlying system type of the specified Type.

C#

```
public virtual bool Equals (Type? o);
```

Parameters

o Type

The object whose underlying system type is to be compared with the underlying system type of the current Type.

Returns

Boolean

`true` if the underlying system type of `o` is the same as the underlying system type of the current Type; otherwise, `false`.

Examples

The following example uses `Equals` to compare two types.

C#

```
using System;
using System.Reflection;

class Example
{
    public static void Main()
    {

        Type a = typeof(System.String);
        Type b = typeof(System.Int32);

        Console.WriteLine("{0} == {1}: {2}", a, b, a.Equals(b));

        // The Type objects in a and b are not equal,
        // because they represent different types.

        a = typeof(Example);
        b = new Example().GetType();

        Console.WriteLine("{0} is equal to {1}: {2}", a, b, a.Equals(b));

        // The Type objects in a and b are equal,
        // because they both represent type Example.

        b = typeof(Type);

        Console.WriteLine("typeof({0}).Equals(typeof({1})): {2}", a, b,
a.Equals(b));

        // The Type objects in a and b are not equal,
        // because variable a represents type Example
        // and variable b represents type Type.

        //Console.ReadLine();
    }
}

//
/* This code example produces the following output:
    System.String == System.Int32: False
    Example is equal to Example: True
```

```
    typeof(Example).Equals(typeof(System.Type)): False
*/
```

See also

- UnderlyingSystemType

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(Object)

Determines if the underlying system type of the current Type object is the same as the underlying system type of the specified Object.

C#

```
public override bool Equals (object? o);
```

Parameters

o Object

The object whose underlying system type is to be compared with the underlying system type of the current Type. For the comparison to succeed, `o` must be able to be cast or converted to an object of type Type.

Returns

Boolean

`true` if the underlying system type of `o` is the same as the underlying system type of the current Type; otherwise, `false`. This method also returns `false` if:

- `o` is `null`.
- `o` cannot be cast or converted to a Type object.

Examples

The following example uses Equals(Object) to compare various Type object instances with various Object instances.

C#

```
using System;
using System.Collections.Generic;
using System.Reflection;

public class Example
{
   public static void Main()
   {
      Type t =typeof(int);
      Object obj1 = typeof(int).GetTypeInfo();
      IsEqualTo(t, obj1);

      Object obj2 = typeof(String);
      IsEqualTo(t, obj2);

      t = typeof(Object);
      Object obj3 = typeof(Object);
      IsEqualTo(t, obj3);

      t = typeof(List<>);
      Object obj4 = (new List<String>()).GetType();
      IsEqualTo(t, obj4);

      t = typeof(Type);
      Object obj5 = null;
      IsEqualTo(t, obj5);
   }

   private static void IsEqualTo(Type t, Object inst)
   {
      Type t2 = inst as Type;
      if (t2 != null)
         Console.WriteLine("{0} = {1}: {2}", t.Name, t2.Name,
                           t.Equals(t2));
      else
         Console.WriteLine("Cannot cast the argument to a type.");
```

```
        Console.WriteLine();
    }
}
// The example displays the following output:
//       Int32 = Int32: True
//
//       Int32 = String: False
//
//       Object = Object: True
//
//       List`1 = List`1: False
//
//       Cannot cast the argument to a type.
```

Two things are particularly worth noting about the example:

- The comparison of a Type object that represents an integer with a TypeInfo object that represents an integer return `true` because TypeInfo is derived from Type.
- The comparison of a Type object that represents a IList<T> object (an open generic type) with a `List(Of String)` object (a closed generic type) returns `false`.

Remarks

This method overrides Object.Equals. It casts `o` to an object of type Type and calls the Type.Equals(Type) method.

Type.FindInterfaces(TypeFilter, Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an array of Type objects representing a filtered list of interfaces implemented or inherited by the current Type.

C#

```
public virtual Type[] FindInterfaces (System.Reflection.TypeFilter filter,
object? filterCriteria);
```

Parameters

`filter` TypeFilter

The delegate that compares the interfaces against `filterCriteria`.

`filterCriteria` Object

The search criteria that determines whether an interface should be included in the returned array.

Returns

Type[]

An array of Type objects representing a filtered list of the interfaces implemented or inherited by the current Type, or an empty array if no interfaces matching the filter are implemented or inherited by the current Type.

Exceptions

ArgumentNullException

`filter` is `null`.

TargetInvocationException

A static initializer is invoked and throws an exception.

Examples

The following example finds the specified interface implemented or inherited by the specified type, and then displays the interface names.

C#

```
using System;
using System.Xml;
using System.Reflection;

public class MyFindInterfacesSample
{
    public static void Main()
    {
        try
        {
            XmlDocument myXMLDoc = new XmlDocument();
            myXMLDoc.LoadXml("<book genre='novel' ISBN='1-861001-57-5'>" +
                "<title>Pride And Prejudice</title>" + "</book>");
            Type myType = myXMLDoc.GetType();

            // Specify the TypeFilter delegate that compares the
            // interfaces against filter criteria.
            TypeFilter myFilter = new TypeFilter(MyInterfaceFilter);
            String[] myInterfaceList = new String[2]
                {"System.Collections.IEnumerable",
                "System.Collections.ICollection"};
            for(int index=0; index < myInterfaceList.Length; index++)
            {
                Type[] myInterfaces = myType.FindInterfaces(myFilter,
                    myInterfaceList[index]);
                if (myInterfaces.Length > 0)
                {
                    Console.WriteLine("\n{0} implements the interface {1}.",
                        myType, myInterfaceList[index]);
                    for(int j =0;j < myInterfaces.Length;j++)
                        Console.WriteLine("Interfaces supported: {0}.",
                            myInterfaces[j].ToString());
                }
                else
                    Console.WriteLine(
                        "\n{0} does not implement the interface {1}.",
                        myType,myInterfaceList[index]);
            }
        }
        catch(ArgumentNullException e)
        {
```

```
            Console.WriteLine("ArgumentNullException: " + e.Message);
        }
        catch(TargetInvocationException e)
        {
            Console.WriteLine("TargetInvocationException: " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: " + e.Message);
        }
    }

    public static bool MyInterfaceFilter(Type typeObj,Object criteriaObj)
    {
        if(typeObj.ToString() == criteriaObj.ToString())
            return true;
        else
            return false;
    }
}
```

Remarks

This method can be overridden by a derived class.

The Module.FilterTypeName and Module.FilterTypeNameIgnoreCase delegates supplied by the System.Reflection.Module class may also be used, in lieu of the System.Reflection.TypeFilter delegate.

All of the interfaces implemented by this class are considered during the search, whether declared by a base class or this class itself.

This method searches the base class hierarchy, returning each of the matching interfaces each class implements as well as all the matching interfaces each of those interfaces implements (that is, the transitive closure of the matching interfaces is returned). No duplicate interfaces are returned.

If the current Type represents a type parameter in the definition of a generic type or generic method, FindInterfaces searches all the interfaces declared in the constraints on the type parameter, and all interfaces inherited through the interfaces declared in the constraints. If the current Type represents a type argument of a generic type, FindInterfaces searches all the interfaces implemented by the type, whether or not they match constraints.

ⓘ **Note**

FindInterfaces can return generic interfaces, even on types that are not generic. For example, a nongeneric type might implement `IEnumerable<int>` (`IEnumerable(Of Integer)` in Visual Basic).

Type.FindMembers(MemberTypes, BindingFlags, MemberFilter, Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a filtered array of MemberInfo objects of the specified member type.

C#

```
public virtual System.Reflection.MemberInfo[] FindMembers
(System.Reflection.MemberTypes memberType, System.Reflection.BindingFlags
bindingAttr, System.Reflection.MemberFilter? filter, object?
filterCriteria);
```

Parameters

`memberType` MemberTypes

A bitwise combination of the enumeration values that indicates the type of member to search for.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`filter` MemberFilter

The delegate that does the comparisons, returning `true` if the member currently being inspected matches the `filterCriteria` and `false` otherwise.

`filterCriteria` Object

The search criteria that determines whether a member is returned in the array of `MemberInfo` objects.

The fields of `FieldAttributes`, `MethodAttributes`, and `MethodImplAttributes` can be used in conjunction with the `FilterAttribute` delegate supplied by this class.

Returns

MemberInfo[]

A filtered array of MemberInfo objects of the specified member type.

-or-

An empty array if the current Type does not have members of type `memberType` that match the filter criteria.

Exceptions

ArgumentNullException

`filter` is `null`.

Examples

The following example finds all the members in a class that match the specified search criteria, and then displays the matched members.

C#

```
using System;
using System.Reflection;

class MyFindMembersClass
{
    public static void Main()
    {
        Object objTest = new Object();
        Type objType = objTest.GetType ();
        MemberInfo[] arrayMemberInfo;
        try
        {
            //Find all static or public methods in the Object class that
match the specified name.
            arrayMemberInfo = objType.FindMembers(MemberTypes.Method,
                BindingFlags.Public | BindingFlags.Static|
BindingFlags.Instance,
                new MemberFilter(DelegateToSearchCriteria),
```

```
                "ReferenceEquals");

            for(int index=0;index < arrayMemberInfo.Length ;index++)
                Console.WriteLine ("Result of FindMembers -\t"+
arrayMemberInfo[index].ToString() +"\n");
        }
        catch (Exception e)
        {
            Console.WriteLine ("Exception : " + e.ToString() );
        }
    }
    public static bool DelegateToSearchCriteria(MemberInfo objMemberInfo,
Object objSearch)
    {
        // Compare the name of the member function with the filter criteria.
        if(objMemberInfo.Name.ToString() == objSearch.ToString())
            return true;
        else
            return false;
    }
}
/* The example produces the following output:

Result of FindMembers - Boolean ReferenceEquals(System.Object,
System.Object)
*/
```

Remarks

This method can be overridden by a derived class.

Members include properties, methods, fields, events, and so on.

For the `FindMembers` method to successfully retrieve member information, the `bindingAttr` argument must include at least one of BindingFlags.Instance and BindingFlags.Static, along with at least one of BindingFlags.NonPublic and BindingFlags.Public.

The following BindingFlags filter flags can be used to define which members to include in the search:

- Specify `BindingFlags.Instance` to include instance members in the search.
- Specify `BindingFlags.Static` to include static members in the search.
- Specify `BindingFlags.Public` to include public members in the search.

- Specify `BindingFlags.NonPublic` to include non-public members (that is, private, internal, and protected members) in the search.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

See System.Reflection.BindingFlags for more information.

To get the class initializer (static constructor) using this method, you must specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

If the current Type represents a type parameter of a generic type or generic method, FindMembers processes any members declared by the class constraint and the interface constraints of the type parameter.

The `filter` argument can be a custom delegate of type MemberFilter, or it can be one of the following predefined delegates:

- Type.FilterAttribute, which uses aFieldAttributes, MethodAttributes, or MethodImplAttributes bitmask as the `filterCriteria` value.

- Type.FilterName, which performs a case-sensitive comparison of each member name with the string passed to `filterCriteria`.

- Type.FilterNameIgnoreCase, which performs a case-insensitive comparison of each member name with the string passed to `filterCriteria`.

Type.GetArrayRank Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of dimensions in an array.

C#

```
public virtual int GetArrayRank ();
```

Returns

Int32

An integer that contains the number of dimensions in the current type.

Exceptions

NotSupportedException

The functionality of this method is unsupported in the base class and must be implemented in a derived class instead.

ArgumentException

The current type is not an array.

Examples

The following example displays the number of dimensions in an array.

C#

```
using System;

class MyArrayRankSample
{
    public static void Main()
    {
        try
```

```
        {
            int[,,] myArray = new int[,,] {{{12,2,35},{300,78,33}},
{{92,42,135},{30,7,3}}};
            Type myType = myArray.GetType();

            Console.WriteLine("Contents of myArray: {{{12,2,35},
{300,78,33}},{{92,42,135},{30,7,3}}}");
            Console.WriteLine("myArray has {0} dimensions.",
myType.GetArrayRank());
        }
        catch(NotSupportedException e)
        {
            Console.WriteLine("NotSupportedException raised.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception raised.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
    }
}
```

Type.GetAttributeFlagsImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the Attributes property and gets a bitwise combination of enumeration values that indicate the attributes associated with the Type.

C#

```
protected abstract System.Reflection.TypeAttributes GetAttributeFlagsImpl
();
```

Returns

TypeAttributes

A TypeAttributes object representing the attribute set of the Type.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.GetConstructor Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific constructor of the current Type.

Overloads

Expand table

GetConstructor(BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	Searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetConstructor(BindingFlags, Binder, Type[], ParameterModifier[])	Searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints.
GetConstructor(BindingFlags, Type[])	Searches for a constructor whose parameters match the specified argument types, using the specified binding constraints.
GetConstructor(Type[])	Searches for a public instance constructor whose parameters match the types in the specified array.

GetConstructor(BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])

Searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.

```
C#
```

```
public System.Reflection.ConstructorInfo? GetConstructor
(System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, System.Reflection.CallingConventions callConvention, Type[]
types, System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`callConvention` CallingConventions

The object that specifies the set of rules to use regarding the order and layout of arguments, how the return value is passed, what registers are used for arguments, and the stack is cleaned up.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the constructor to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a constructor that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

ConstructorInfo

An object representing the constructor that matches the specified requirements, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

Examples

The following example obtains the type of `MyClass`, gets the ConstructorInfo object, and displays the constructor signature.

C#

```
using System;
using System.Reflection;
using System.Security;

public class MyClass1
{
    public MyClass1(int i){}
    public static void Main()
    {
        try
        {
            Type  myType = typeof(MyClass1);
            Type[] types = new Type[1];
            types[0] = typeof(int);
```

```
            // Get the public instance constructor that takes an integer
parameter.
            ConstructorInfo constructorInfoObj = myType.GetConstructor(
                BindingFlags.Instance | BindingFlags.Public, null,
                CallingConventions.HasThis, types, null);
            if(constructorInfoObj != null)
            {
                Console.WriteLine("The constructor of MyClass1 that is a
public " +
                    "instance method and takes an integer as a parameter
is: ");
                Console.WriteLine(constructorInfoObj.ToString());
            }
            else
            {
                Console.WriteLine("The constructor of MyClass1 that is a
public instance " +
                    "method and takes an integer as a parameter is not
available.");
            }
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("ArgumentNullException: " + e.Message);
        }
        catch(ArgumentException e)
        {
            Console.WriteLine("ArgumentException: " + e.Message);
        }
        catch(SecurityException e)
        {
            Console.WriteLine("SecurityException: " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: " + e.Message);
        }
    }
}
```

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

If an exact match does not exist, the `binder` will attempt to coerce the parameter types specified in the `types` array in order to select a match. If the `binder` is unable

to select a match, then `null` is returned.

The following BindingFlags filter flags can be used to define which constructors to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public constructors in the search.
- Specify `BindingFlags.NonPublic` to include non-public constructors (that is, private, internal, and protected constructors) in the search.

See System.Reflection.BindingFlags for more information.

To get the class initializer (static constructor) using this method, you must specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

> **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the ConstructorInfo with the type parameters replaced by the appropriate type arguments. If the current Type represents a type parameter in the definition of a generic type or generic method, this method always returns `null`.

.NET Standard	2.0, 2.1

GetConstructor(BindingFlags, Binder, Type[], ParameterModifier[])

Searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints.

C#

```
public System.Reflection.ConstructorInfo? GetConstructor
(System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, Type[] types, System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the constructor to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a constructor that takes no parameters.

-or-

EmptyTypes.

modifiers ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the parameter type array. The default binder does not process this parameter.

Returns

ConstructorInfo

A ConstructorInfo object representing the constructor that matches the specified requirements, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

Examples

The following example obtains the type of `MyClass`, gets the ConstructorInfo object, and displays the constructor signature.

C#

```
using System;
using System.Reflection;
using System.Security;

public class MyClass1
{
    public MyClass1(int i){}
    public static void Main()
    {
        try
        {
            Type myType = typeof(MyClass1);
            Type[] types = new Type[1];
            types[0] = typeof(int);
            // Get the constructor that is public and takes an integer
parameter.
            ConstructorInfo constructorInfoObj = myType.GetConstructor(
                BindingFlags.Instance | BindingFlags.Public, null, types,
null);
            if (constructorInfoObj != null )
            {
                Console.WriteLine("The constructor of MyClass1 that is
public " +
                    "and takes an integer as a parameter is:");
                Console.WriteLine(constructorInfoObj.ToString());
            }
            else
            {
                Console.WriteLine("The constructor of the MyClass1 that
is public " +
                    "and takes an integer as a parameter is not
available.");
            }
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("ArgumentNullException: " + e.Message);
        }
        catch(ArgumentException e)
        {
            Console.WriteLine("ArgumentException: " + e.Message);
        }
        catch(SecurityException e)
        {
            Console.WriteLine("SecurityException: " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: " + e.Message);
```

```
        }
    }
}
```

Remarks

If an exact match does not exist, the `binder` will attempt to coerce the parameter types specified in the `types` array in order to select a match. If the `binder` is unable to select a match, then `null` is returned.

The following BindingFlags filter flags can be used to define which constructors to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public constructors in the search.
- Specify `BindingFlags.NonPublic` to include non-public constructors (that is, private, internal, and protected constructors) in the search.

See System.Reflection.BindingFlags for more information.

To get the class initializer (static constructor) using this method overload, you must specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

> **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the ConstructorInfo with the type parameters replaced by the appropriate type arguments. If the current Type represents a type parameter in the definition of a generic type or generic method, this method always returns `null`.

.NET Standard	2.0, 2.1

GetConstructor(BindingFlags, Type[])

Searches for a constructor whose parameters match the specified argument types, using the specified binding constraints.

C#

```
public System.Reflection.ConstructorInfo? GetConstructor
(System.Reflection.BindingFlags bindingAttr, Type[] types);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted. -or- Default to return `null`.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the constructor to get. -or- An empty array of the type Type (that is, Type[] types = Array.Empty{Type}()) to get a constructor that takes no parameters. -or- EmptyTypes.

Returns

ConstructorInfo

A ConstructorInfo object representing the constructor that matches the specified requirements, if found; otherwise, `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

GetConstructor(Type[])

Searches for a public instance constructor whose parameters match the types in the specified array.

C#

```
public System.Reflection.ConstructorInfo? GetConstructor (Type[] types);
```

Parameters

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the desired constructor.

-or-

An empty array of Type objects, to get a constructor that takes no parameters. Such an empty array is provided by the `static` field EmptyTypes.

Returns

ConstructorInfo

An object representing the public instance constructor whose parameters match the types in the parameter type array, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

Examples

The following example obtains the type of `MyClass`, gets the ConstructorInfo object, and displays the constructor signature.

C#

```
using System;
using System.Reflection;
using System.Security;

public class MyClass1
{
    public MyClass1(){}
    public MyClass1(int i){}

    public static void Main()
    {
        try
        {
            Type myType = typeof(MyClass1);
            Type[] types = new Type[1];
            types[0] = typeof(int);
            // Get the constructor that takes an integer as a parameter.
            ConstructorInfo constructorInfoObj =
myType.GetConstructor(types);
            if (constructorInfoObj != null)
            {
                Console.WriteLine("The constructor of MyClass1 that takes
an " +
                    "integer as a parameter is: ");
                Console.WriteLine(constructorInfoObj.ToString());
            }
            else
            {
                Console.WriteLine("The constructor of MyClass1 that takes
an integer " +
```

```
                    "as a parameter is not available.");
            }
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception caught.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
    }
}
```

Remarks

This method overload looks for public instance constructors and cannot be used to obtain a class initializer (static constructor). To get a class initializer, use an overload that takes BindingFlags, and specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

If the requested constructor is non-public, this method returns `null`.

> **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the ConstructorInfo with the type parameters replaced by the appropriate type arguments. If the current Type represents a type parameter in the definition of a generic type or generic method, this method always returns `null`.

Type.GetConstructorImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, searches for a constructor whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.

C#

```
protected abstract System.Reflection.ConstructorInfo? GetConstructorImpl
(System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, System.Reflection.CallingConventions callConvention, Type[] types,
System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`callConvention` CallingConventions

The object that specifies the set of rules to use regarding the order and layout of arguments, how the return value is passed, what registers are used for arguments, and

the stack is cleaned up.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the constructor to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a constructor that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

ConstructorInfo

A ConstructorInfo object representing the constructor that matches the specified requirements, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

NotSupportedException

The current type is a TypeBuilder or GenericTypeParameterBuilder.

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

If an exact match does not exist, the `binder` will attempt to coerce the parameter types specified in the `types` array in order to select a match. If the `binder` is unable to select a match, then `null` is returned.

The following BindingFlags filter flags can be used to define which constructors to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public constructors in the search.
- Specify `BindingFlags.NonPublic` to include non-public constructors (that is, private, internal, and protected constructors) in the search.

See System.Reflection.BindingFlags for more information.

This method implements GetConstructor.

Applies to

Product	Versions

Type.GetConstructors Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the constructors of the current Type.

Overloads

Expand table

GetConstructors()	Returns all the public constructors defined for the current Type.
GetConstructors(BindingFlags)	When overridden in a derived class, searches for the constructors defined for the current Type, using the specified `BindingFlags`.

Examples

This example shows the output of the GetConstructors() overload from a class that has two instance constructors and one static constructor.

C#

```
using System;
using System.Reflection;

public class t {
    public t() {}
    static t() {}
    public t(int i) {}

    public static void Main() {
        ConstructorInfo[] p = typeof(t).GetConstructors();
        Console.WriteLine(p.Length);

        for (int i=0;i<p.Length;i++) {
            Console.WriteLine(p[i].IsStatic);
        }
    }
}
```

The output of this code is:

Output

```
2
False
False
```

Because the GetConstructors overload uses only Public and Instance, the static constructor is neither counted by the `for` expression nor evaluated by `IsStatic`.

To find static constructors, use the GetConstructors overload, and pass it the combination (logical OR) of BindingFlags.Public, BindingFlags.Static, BindingFlags.NonPublic, BindingFlags.Instance, as shown in the following code example:

C#

```
using System;
using System.Reflection;

public class t {
    public t() {}
    static t() {}
    public t(int i) {}

    public static void Main() {
        ConstructorInfo[] p = typeof(t).GetConstructors(
           BindingFlags.Public | BindingFlags.Static |
           BindingFlags.NonPublic | BindingFlags.Instance);
        Console.WriteLine(p.Length);

        for (int i=0;i<p.Length;i++) {
            Console.WriteLine(p[i].IsStatic);
        }
    }
}
```

Now the output is:

Output

```
3
False
True
False
```

GetConstructors()

Returns all the public constructors defined for the current Type.

```
C#

public System.Reflection.ConstructorInfo[] GetConstructors ();
```

Returns

ConstructorInfo[]

An array of ConstructorInfo objects representing all the public instance constructors defined for the current Type, but not including the type initializer (static constructor). If no public instance constructors are defined for the current Type, or if the current Type represents a type parameter in the definition of a generic type or generic method, an empty array of type ConstructorInfo is returned.

Remarks

In .NET 6 and earlier versions, the GetConstructors method does not return constructors in a particular order, such as declaration order. Your code must not depend on the order in which constructors are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No

Member Type	Static	Non-Static
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

This method overload calls the GetConstructors(BindingFlags) method overload, with BindingFlags.Public | BindingFlags.Instance (BindingFlags.Public `Or` BindingFlags.Instance in Visual Basic). It will not find class initializers (static constructor). To find class initializers, use an overload that takes BindingFlags, and specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

If the current Type represents a constructed generic type, this method returns the ConstructorInfo objects with the type parameters replaced by the appropriate type arguments. For example, if class `C<T>` has a constructor `C(T t1)` (`Sub New(ByVal t1 As T)` in Visual Basic), calling GetConstructors on `C<int>` returns a ConstructorInfo that represents `C(int t1)` in C# (`Sub New(ByVal t1 As Integer)` in Visual Basic).

If the current Type represents a generic type parameter, the GetConstructors method returns an empty array.

See also

- ConstructorInfo
- GetConstructor(BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetConstructors(BindingFlags)

When overridden in a derived class, searches for the constructors defined for the current Type, using the specified `BindingFlags`.

C#

```
public abstract System.Reflection.ConstructorInfo[] GetConstructors
(System.Reflection.BindingFlags bindingAttr);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

ConstructorInfo[]

An array of ConstructorInfo objects representing all constructors defined for the current Type that match the specified binding constraints, including the type initializer if it is defined. Returns an empty array of type ConstructorInfo if no constructors are defined for the current Type, if none of the defined constructors match the binding constraints, or if the current Type represents a type parameter in the definition of a generic type or generic method.

Remarks

`bindingAttr` can be used to specify whether to return only public constructors or both public and non-public constructors.

The following BindingFlags filter flags can be used to define which constructors to include in the search:

- Specify `BindingFlags.Static` along with `BindingFlags.NonPublic` to retrieve the class initializer (static constructor). You can also get the class initializer using the TypeInitializer property.
- Specify `BindingFlags.Instance` along with one or both of `BindingFlags.Public` and `BindingFlags.NonPublic` to retrieve instance constructors.

See System.Reflection.BindingFlags for more information.

In .NET 6 and earlier versions, the GetConstructors method does not return constructors in a particular order, such as declaration order. Your code must not depend on the order in which constructors are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

If the current Type represents a constructed generic type, this method returns the ConstructorInfo objects with the type parameters replaced by the appropriate type arguments. For example, if class `C<T>` has a constructor `C(T t1)` (`Sub New(ByVal t1 As T)` in Visual Basic), calling GetConstructors on `C<int>` returns a ConstructorInfo that represents `C(int t1)` in C# (`Sub New(ByVal t1 As Integer)` in Visual Basic).

If the current Type represents a generic type parameter, the GetConstructors method returns an empty array.

Type.GetDefaultMembers Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for the members defined for the current Type whose DefaultMemberAttribute is set.

C#

```
public virtual System.Reflection.MemberInfo[] GetDefaultMembers ();
```

Returns

MemberInfo[]

An array of MemberInfo objects representing all default members of the current Type.

-or-

An empty array of type MemberInfo, if the current Type does not have default members.

Examples

The following example obtains the default member information of `MyClass` and displays the default members.

C#

```
using System;
using System.Reflection;
using System.IO;

[DefaultMemberAttribute("Age")]
public class MyClass
{
    public void Name(String s) {}
    public int Age
    {
        get
```

```
        {
            return 20;
        }
    }
    public static void Main()
    {
        try
        {
            Type  myType = typeof(MyClass);
            MemberInfo[] memberInfoArray = myType.GetDefaultMembers();
            if (memberInfoArray.Length > 0)
            {
                foreach(MemberInfo memberInfoObj in memberInfoArray)
                {
                    Console.WriteLine("The default member name is: " +
memberInfoObj.ToString());
                }
            }
            else
            {
                Console.WriteLine("No default members are available.");
            }
        }
        catch(InvalidOperationException e)
        {
            Console.WriteLine("InvalidOperationException: " + e.Message);
        }
        catch(IOException e)
        {
            Console.WriteLine("IOException: " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: " + e.Message);
        }
    }
}
```

Remarks

The GetDefaultMembers method does not return members in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which members are returned, because that order varies.

This method can be overridden by a derived class.

Members include properties, methods, fields, events, and so on.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the MemberInfo objects with the type parameters replaced by the appropriate type arguments. For example, if class `C<T>` has a property `P` that returns `T`, calling GetDefaultMembers on `C<int>` returns `int P` in C# (`Property P As Integer` in Visual Basic).

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the members of the class constraint, or the members of Object if there is no class constraint.

Type.GetElementType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the Type of the object encompassed or referred to by the current array, pointer or reference type.

C#

```
public abstract Type? GetElementType ();
```

Returns

Type

The Type of the object encompassed or referred to by the current array, pointer, or reference type, or `null` if the current Type is not an array or a pointer, or is not passed by reference, or represents a generic type or a type parameter in the definition of a generic type or generic method.

Examples

The following example demonstrates using the `GetElementType` method.

C#

```
using System;
class TestGetElementType
{
    public static void Main()
    {
        int[] array = {1,2,3};
        Type t = array.GetType();
        Type t2 = t.GetElementType();
        Console.WriteLine("The element type of {0} is {1}.",array,
t2.ToString());
        TestGetElementType newMe = new TestGetElementType();
        t = newMe.GetType();
        t2 = t.GetElementType();
```

```
        Console.WriteLine("The element type of {0} is {1}.", newMe,
t2==null? "null" : t2.ToString());
    }
}

/* This code produces the following output:

The element type of System.Int32[] is System.Int32.
The element type of TestGetElementType is null.
 */
```

Remarks

This method returns `null` for the Array class.

Type.GetEnumName(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the name of the constant that has the specified value, for the current enumeration type.

```
C#
public virtual string? GetEnumName (object value);
```

Parameters

`value` Object

The value whose name is to be retrieved.

Returns

String

The name of the member of the current enumeration type that has the specified value, or `null` if no such constant is found.

Exceptions

ArgumentException

The current type is not an enumeration.

-or-

`value` is neither of the current type nor does it have the same underlying type as the current type.

ArgumentNullException

`value` is `null`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.GetEnumNames Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the names of the members of the current enumeration type.

C#

```
public virtual string[] GetEnumNames ();
```

Returns

String[]

An array that contains the names of the members of the enumeration.

Exceptions

ArgumentException

The current type is not an enumeration.

Remarks

The elements of the return value array are sorted by the binary values (that is, the unsigned values) of the enumerated constants. If the array contains enumerated constants with the same value, the order of their corresponding names is unspecified.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.GetEnumUnderlyingType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the underlying type of the current enumeration type.

C#

```
public virtual Type GetEnumUnderlyingType ();
```

Returns

Type

The underlying type of the current enumeration.

Exceptions

ArgumentException

The current type is not an enumeration.

-or-

The enumeration type is not valid, because it contains more than one instance field.

Remarks

By default, the underlying type of an enumeration in C# and Visual Basic is Int32. Other integer types can be specified.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.GetEnumValues Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an array of the values of the constants in the current enumeration type.

C#

```
public virtual Array GetEnumValues ();
```

Returns

Array

An array that contains the values. The elements of the array are sorted by the binary values (that is, the unsigned values) of the enumeration constants.

Exceptions

ArgumentException

The current type is not an enumeration.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.GetEnumValuesAsUnderlyingType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Retrieves an array of the values of the underlying type constants of this enumeration type.

```
C#
public virtual Array GetEnumValuesAsUnderlyingType ();
```

Returns

Array

An array that contains the values of the underlying type constants in this enumeration type.

Exceptions

ArgumentException

This type is not an enumeration type.

Remarks

You can use this method to get enumeration values when it's hard to create an array of the enumeration type. For example, you might use this method for the MetadataLoadContext enumeration or on a platform where run-time code generation is not available.

Applies to

Product	Versions
.NET	7, 8, 9

Type.GetEvent Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific event declared or inherited by the current Type.

Overloads

Expand table

GetEvent(String, BindingFlags)	When overridden in a derived class, returns the EventInfo object representing the specified event, using the specified binding constraints.
GetEvent(String)	Returns the EventInfo object representing the specified public event.

GetEvent(String, BindingFlags)

When overridden in a derived class, returns the EventInfo object representing the specified event, using the specified binding constraints.

C#

```
public abstract System.Reflection.EventInfo? GetEvent (string name,
System.Reflection.BindingFlags bindingAttr);
```

Parameters

name String

The string containing the name of an event which is declared or inherited by the current Type.

bindingAttr BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

Returns

EventInfo

The object representing the specified event that is declared or inherited by the current Type, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

Examples

The following code example uses the GetEvent(String, BindingFlags) method to search a type for a public or non-public event named "Click" that is not `static` (`Shared` in Visual Basic).

C#

```
using System;
using System.Reflection;
using System.Security;

class MyEventExample
{
    public static void Main()
    {
        try
        {

            // Creates a bitmask based on BindingFlags.
            BindingFlags myBindingFlags = BindingFlags.Instance |
BindingFlags.Public | BindingFlags.NonPublic;
            Type myTypeBindingFlags =
typeof(System.Windows.Forms.Button);
            EventInfo myEventBindingFlags =
myTypeBindingFlags.GetEvent("Click", myBindingFlags);
            if(myEventBindingFlags != null)
            {
                Console.WriteLine("Looking for the Click event in the
Button class with the specified BindingFlags.");
                Console.WriteLine(myEventBindingFlags.ToString());
            }
```

```
            else
            {
                Console.WriteLine("The Click event is not available with
the Button class.");
            }
        }
        catch(SecurityException e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Message :"+e.Message);
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Message :"+e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("The following exception was raised :
{0}",e.Message);
        }
    }
}
```

Remarks

The following BindingFlags filter flags can be used to define which events to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public events in the search.
- Specify `BindingFlags.NonPublic` to include non-public events (that is, private, internal, and protected events) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the events declared on the Type, not events that were simply inherited.

See System.Reflection.BindingFlags for more information.

An event is considered public to reflection if it has at least one method or accessor that is public. Otherwise the event is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

If the current Type represents a constructed generic type, this method returns the EventInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the events of the class constraint.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetEvent(String)

Returns the EventInfo object representing the specified public event.

C#

```
public System.Reflection.EventInfo? GetEvent (string name);
```

Parameters

`name` String

The string containing the name of an event that is declared or inherited by the current Type.

Returns

EventInfo

The object representing the specified public event that is declared or inherited by the current Type, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

Examples

The following example creates an EventInfo object and gets the event for a button class for the specified event.

C#

```
using System;
using System.Reflection;
using System.Security;

class MyEventExample
{
    public static void Main()
    {
        try
        {

            Type myType = typeof(System.Windows.Forms.Button);
            EventInfo myEvent = myType.GetEvent("Click");
            if(myEvent != null)
            {
                Console.WriteLine("Looking for the Click event in the
Button class.");
                Console.WriteLine(myEvent.ToString());
            }
            else
            {
                Console.WriteLine("The Click event is not available in
the Button class.");
```

```
            }
        }
        catch(SecurityException e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Message :"+e.Message);
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Message :"+e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("The following exception was raised :
{0}",e.Message);
        }
    }
}
```

Remarks

An event is considered public to reflection if it has at least one method or accessor that is public. Otherwise the event is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

The search for `name` is case-sensitive. The search includes public static and public instance events.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

Member Type	Static	Non-Static
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the EventInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the events of the class constraint.

Type.GetEvents Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the events that are declared or inherited by the current Type.

Overloads

Expand table

GetEvents()	Returns all the public events that are declared or inherited by the current Type.
GetEvents(BindingFlags)	When overridden in a derived class, searches for events that are declared or inherited by the current Type, using the specified binding constraints.

GetEvents()

Returns all the public events that are declared or inherited by the current Type.

C#

```
public virtual System.Reflection.EventInfo[] GetEvents ();
```

Returns

EventInfo[]

An array of EventInfo objects representing all the public events which are declared or inherited by the current Type.

-or-

An empty array of type EventInfo, if the current Type does not have public events.

Examples

The following example obtains an array of EventInfo objects, gets all the events for a `Button` class, and displays the event names. To compile the Visual Basic example, use the following command line:

```
vbc type_getevents1.vb /r:System.Windows.Forms.dll /r:System.dll
```

C#

```
using System;
using System.Reflection;
using System.Security;

class EventsSample
{
    public static void Main()
    {
        try
        {
            // Creates a bitmask based on BindingFlags.
            BindingFlags myBindingFlags = BindingFlags.Instance |
BindingFlags.Public;
            Type myTypeEvent = typeof(System.Windows.Forms.Button);
            EventInfo[] myEventsBindingFlags =
myTypeEvent.GetEvents(myBindingFlags);
            Console.WriteLine("\nThe events on the Button class with the
specified BindingFlags are : ");
            for (int index = 0; index < myEventsBindingFlags.Length;
index++)
            {

Console.WriteLine(myEventsBindingFlags[index].ToString());
            }
        }
        catch(SecurityException e)
        {
            Console.WriteLine("SecurityException :" + e.Message);
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("ArgumentNullException : " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception : " + e.Message);
        }
    }
}
```

Remarks

An event is considered public to reflection if it has at least one method or accessor that is public. Otherwise the event is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

In .NET 6 and earlier versions, the GetEvents method does not return events in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which events are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

This method can be overridden by a derived class.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the EventInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the events of the class constraint.

.NET Standard	2.0, 2.1

GetEvents(BindingFlags)

When overridden in a derived class, searches for events that are declared or inherited by the current Type, using the specified binding constraints.

C#

```
public abstract System.Reflection.EventInfo[] GetEvents
(System.Reflection.BindingFlags bindingAttr);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

EventInfo[]

An array of EventInfo objects representing all events that are declared or inherited by the current Type that match the specified binding constraints.

-or-

An empty array of type EventInfo, if the current Type does not have events, or if none of the events match the binding constraints.

Examples

The following example obtains an array of EventInfo objects that match the specified binding flags, gets all the events for a `Button` class, and displays the event names. To compile the Visual Basic example, use the following command line:

```
vbc type_getevents2.vb /r:System.Windows.Forms.dll /r:System.dll
```

C#

```
using System;
using System.Reflection;
using System.Security;

class EventsSample
{
    public static void Main()
    {
        try
        {
            // Create a bitmask based on BindingFlags.
            BindingFlags myBindingFlags = BindingFlags.Instance |
BindingFlags.Public;
            Type myTypeEvent = typeof(System.Windows.Forms.Button);
            EventInfo[] myEventsBindingFlags =
myTypeEvent.GetEvents(myBindingFlags);
```

```
            Console.WriteLine("\nThe events on the Button class with the
specified BindingFlags are:");
            for (int index = 0; index < myEventsBindingFlags.Length;
index++)
            {

Console.WriteLine(myEventsBindingFlags[index].ToString());
            }
        }
        catch(SecurityException e)
        {
            Console.WriteLine("SecurityException:" + e.Message);
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("ArgumentNullException: " + e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception: " + e.Message);
        }
    }
}
```

Remarks

In .NET 6 and earlier versions, the GetEvents method does not return events in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which events are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following BindingFlags filter flags can be used to define which events to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public events in the search.
- Specify `BindingFlags.NonPublic` to include non-public events (that is, private, internal, and protected events) in the search. Only protected and internal events on base classes are returned; private events on base classes are not returned.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not

included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.DeclaredOnly` to search only the events declared on the Type, not events that were simply inherited.

See System.Reflection.BindingFlags for more information.

An event is considered public to reflection if it has at least one method or accessor that is public. Otherwise the event is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

If the current Type represents a constructed generic type, this method returns the EventInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the events of the class constraint.

Type.GetField Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific field of the current Type.

Overloads

Expand table

GetField(String)	Searches for the public field with the specified name.
GetField(String, BindingFlags)	Searches for the specified field, using the specified binding constraints.

GetField(String)

Searches for the public field with the specified name.

C#

```
public System.Reflection.FieldInfo? GetField (string name);
```

Parameters

`name` String

The string containing the name of the data field to get.

Returns

FieldInfo

An object representing the public field with the specified name, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

NotSupportedException

This Type object is a TypeBuilder whose CreateType() method has not yet been called.

Examples

The following example gets the `Type` object for the specified class, obtains the FieldInfo object for the field, and displays the value of the field.

C#

```
using System;
using System.Reflection;

public class MyFieldClassA
{
    public string Field = "A Field";
}

public class MyFieldClassB
{
    private string field = "B Field";
    public string Field
    {
        get
        {
            return field;
        }
        set
        {
            if (field!=value)
            {
                field=value;
            }
        }
    }
}

public class MyFieldInfoClass
{
    public static void Main()
    {
        MyFieldClassB myFieldObjectB = new MyFieldClassB();
        MyFieldClassA myFieldObjectA = new MyFieldClassA();
```

```
        Type myTypeA = typeof(MyFieldClassA);
        FieldInfo myFieldInfo = myTypeA.GetField("Field");

        Type myTypeB = typeof(MyFieldClassB);
        FieldInfo myFieldInfo1 = myTypeB.GetField("field",
            BindingFlags.NonPublic | BindingFlags.Instance);

        Console.WriteLine("The value of the public field is: '{0}'",
            myFieldInfo.GetValue(myFieldObjectA));
        Console.WriteLine("The value of the private field is: '{0}'",
            myFieldInfo1.GetValue(myFieldObjectB));
    }
}
```

Remarks

The search for `name` is case-sensitive. The search includes public static and public instance fields.

If the current Type represents a constructed generic type, this method returns the FieldInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the fields of the class constraint.

.NET Standard	2.0, 2.1

GetField(String, BindingFlags)

Searches for the specified field, using the specified binding constraints.

```
C#

public abstract System.Reflection.FieldInfo? GetField (string name,
System.Reflection.BindingFlags bindingAttr);
```

Parameters

`name` String

The string containing the name of the data field to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

Returns

FieldInfo

An object representing the field that matches the specified requirements, if found; otherwise, `null`.

Implements

GetField(String, BindingFlags)

Exceptions

ArgumentNullException

`name` is `null`.

Examples

The following example gets the `Type` object for the specified class, obtains the FieldInfo object for the field that matches the specified binding flags, and displays

the value of the field.

C#

```
using System;
using System.Reflection;

public class MyFieldClassA
{
    public string Field = "A Field";
}

public class MyFieldClassB
{
    private string field = "B Field";
    public string Field
    {
        get
        {
            return field;
        }
        set
        {
            if (field!=value)
            {
                field=value;
            }
        }
    }
}

public class MyFieldInfoClass
{
    public static void Main()
    {
        MyFieldClassB myFieldObjectB = new MyFieldClassB();
        MyFieldClassA myFieldObjectA = new MyFieldClassA();

        Type myTypeA = typeof(MyFieldClassA);
        FieldInfo myFieldInfo = myTypeA.GetField("Field");

        Type myTypeB = typeof(MyFieldClassB);
        FieldInfo myFieldInfo1 = myTypeB.GetField("field",
            BindingFlags.NonPublic | BindingFlags.Instance);

        Console.WriteLine("The value of the public field is: '{0}'",
            myFieldInfo.GetValue(myFieldObjectA));
        Console.WriteLine("The value of the private field is: '{0}'",
            myFieldInfo1.GetValue(myFieldObjectB));
    }
}
```

Remarks

Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

The following BindingFlags filter flags can be used to define which fields to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.

- Specify `BindingFlags.Public` to include public fields in the search.

- Specify `BindingFlags.NonPublic` to include non-public fields (that is, private, internal, and protected fields) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the fields declared on the Type, not fields that were simply inherited.

See System.Reflection.BindingFlags for more information.

If the current Type represents a constructed generic type, this method returns the FieldInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the fields of the class constraint.

Type.GetFields Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the fields of the current Type.

Overloads

Expand table

GetFields()	Returns all the public fields of the current Type.
GetFields(BindingFlags)	When overridden in a derived class, searches for the fields defined for the current Type, using the specified binding constraints.

GetFields()

Returns all the public fields of the current Type.

C#

```
public System.Reflection.FieldInfo[] GetFields ();
```

Returns

FieldInfo[]

An array of FieldInfo objects representing all the public fields defined for the current Type.

-or-

An empty array of type FieldInfo, if no public fields are defined for the current Type.

Examples

The following example shows a use of the `GetFields()` method.

```C#
using System;
using System.Reflection;
using System.ComponentModel.Design;

class FieldInfo_IsSpecialName
{
    public static void Main()
    {
        try
        {
            // Get the type handle of a specified class.
            Type myType = typeof(ViewTechnology);

            // Get the fields of the specified class.
            FieldInfo[] myField = myType.GetFields();

            Console.WriteLine("\nDisplaying fields that have SpecialName
attributes:\n");
            for(int i = 0; i < myField.Length; i++)
            {
                // Determine whether or not each field is a special name.
                if(myField[i].IsSpecialName)
                {
                    Console.WriteLine("The field {0} has a SpecialName
attribute.",
                        myField[i].Name);
                }
            }
        }
        catch(Exception e)
        {
            Console.WriteLine("Exception : {0} " , e.Message);
        }
    }
}
```

Remarks

In .NET 6 and earlier versions, the GetFields method does not return fields in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which fields are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the FieldInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the public fields of the class constraint.

.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetFields(BindingFlags)

When overridden in a derived class, searches for the fields defined for the current Type, using the specified binding constraints.

C#

```
public abstract System.Reflection.FieldInfo[] GetFields
(System.Reflection.BindingFlags bindingAttr);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

FieldInfo[]

An array of FieldInfo objects representing all fields defined for the current Type that match the specified binding constraints.

-or-

An empty array of type FieldInfo, if no fields are defined for the current Type, or if none of the defined fields match the binding constraints.

Implements

GetFields(BindingFlags)

Examples

The following example shows a use of the `GetFields(BindingFlags)` method.

C#

```
using System;
using System.Reflection;

class AttributesSample
{
    public void Mymethod (int int1m, out string str2m, ref string str3m)
    {
        str2m = "in Mymethod";
    }

    public static int Main(string[] args)
    {
        Console.WriteLine ("Reflection.MethodBase.Attributes Sample");

        // Get the type.
        Type MyType = Type.GetType("AttributesSample");

        // Get the method Mymethod on the type.
        MethodBase Mymethodbase = MyType.GetMethod("Mymethod");

        // Display the method name.
        Console.WriteLine("Mymethodbase = " + Mymethodbase);

        // Get the MethodAttribute enumerated value.
        MethodAttributes Myattributes = Mymethodbase.Attributes;

        // Display the flags that are set.
        PrintAttributes(typeof(System.Reflection.MethodAttributes), (int)
Myattributes);
        return 0;
    }

    public static void PrintAttributes(Type attribType, int iAttribValue)
    {
        if (!attribType.IsEnum)
        {
            Console.WriteLine("This type is not an enum.");
```

```
            return;
        }

        FieldInfo[] fields = attribType.GetFields(BindingFlags.Public |
BindingFlags.Static);
        for (int i = 0; i < fields.Length; i++)
        {
            int fieldvalue = (int)fields[i].GetValue(null);
            if ((fieldvalue & iAttribValue) == fieldvalue)
            {
                Console.WriteLine(fields[i].Name);
            }
        }
    }
}
```

Remarks

For the `GetFields(BindingFlags)` overload to successfully retrieve property information, the `bindingAttr` argument must include at least one of BindingFlags.Instance and BindingFlags.Static, along with at least one of BindingFlags.NonPublic and BindingFlags.Public.

The following BindingFlags filter flags can be used to define which fields to include in the search:

- Specify `BindingFlags.Instance` to include instance methods.
- Specify `BindingFlags.Static` to include static methods.
- Specify `BindingFlags.Public` to include public fields in the search.
- Specify `BindingFlags.NonPublic` to include non-public fields (that is, private, internal, and protected fields) in the search. Only protected and internal fields on base classes are returned; private fields on base classes are not returned.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.
- Specify `BindingFlags.Default` alone to return an empty PropertyInfo array.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.DeclaredOnly` to search only the fields declared on the Type, not fields that were simply inherited.

See System.Reflection.BindingFlags for more information.

In .NET 6 and earlier versions, the GetFields method does not return fields in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which fields are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

If the current Type represents a constructed generic type, this method returns the FieldInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the public fields of the class constraint.

Type.GetFunctionPointerCallingConventions Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the calling conventions of the current function pointer Type.

```
C#
public virtual Type[] GetFunctionPointerCallingConventions ();
```

Returns

Type[]

An array of Type objects representing all the calling conventions for the current function pointer Type.

-or-

An empty array of type Type, if no calling conventions are defined for the current function pointer Type.

-or-

An empty array of type Type, if the current function pointer Type is not a modified Type. A modified Type is obtained from GetModifiedFieldType(), GetModifiedPropertyType(), or GetModifiedParameterType().

Exceptions

InvalidOperationException

The current type is not a function pointer. That is, the IsFunctionPointer property returns `false`.

Remarks

This method is provided for designers of managed compilers. For more information on custom modifiers, see classes in the System.Runtime.CompilerServices namespace.

Type.GetFunctionPointerParameterTypes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the parameter types of the current function pointer Type.

```
C#

public virtual Type[] GetFunctionPointerParameterTypes ();
```

Returns

Type[]

An array of Type objects representing all the parameter types for the current function pointer Type.

-or-

An empty array of type Type, if no parameters are defined for the current function pointer Type.

Exceptions

InvalidOperationException

The current type is not a function pointer. That is, the IsFunctionPointer property returns `false`.

Type.GetFunctionPointerReturnType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the return type of the current function pointer Type.

```
C#
public virtual Type GetFunctionPointerReturnType ();
```

Returns

Type

A Type object representing the return type for the current function pointer Type.

Exceptions

InvalidOperationException

The current type is not a function pointer. That is, the IsFunctionPointer property returns `false`.

Applies to

Product	Versions
.NET	8, 9

Type.GetGenericArguments Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an array of Type objects that represent the type arguments of a closed generic type or the type parameters of a generic type definition.

```
C#

public virtual Type[] GetGenericArguments ();
```

Returns

Type[]

An array of Type objects that represent the type arguments of a generic type. Returns an empty array if the current type is not a generic type.

Exceptions

NotSupportedException

The invoked method is not supported in the base class. Derived classes must provide an implementation.

Examples

The following code example uses the GetGenericArguments method to display the type arguments of a constructed type and the type parameters of its generic type definition.

This code example is part of a larger example provided for the IsGenericTypeDefinition property. See the larger example for sample output.

```
C#

if (t.IsGenericType)
{
    // If this is a generic type, display the type arguments.
    //
```

```
    Type[] typeArguments = t.GetGenericArguments();

    Console.WriteLine("\tList type arguments ({0}):",
        typeArguments.Length);

    foreach (Type tParam in typeArguments)
    {
        // If this is a type parameter, display its
        // position.
        //
        if (tParam.IsGenericParameter)
        {
            Console.WriteLine("\t\t{0}\t(unassigned - parameter position
{1})",
                tParam,
                tParam.GenericParameterPosition);
        }
        else
        {
            Console.WriteLine("\t\t{0}", tParam);
        }
    }
}
```

Remarks

The array elements are returned in the order in which they appear in the list of type arguments for the generic type.

- If the current type is a closed constructed type (that is, the ContainsGenericParameters property returns `false`), the array returned by the GetGenericArguments method contains the types that have been assigned to the generic type parameters of the generic type definition.
- If the current type is a generic type definition, the array contains the type parameters.
- If the current type is an open constructed type (that is, the ContainsGenericParameters property returns `true`) in which specific types have not been assigned to all of the type parameters and type parameters of enclosing generic types or methods, the array contains both types and type parameters. Use the IsGenericParameter property to tell them apart. For a demonstration of this scenario, see the code example for the ContainsGenericParameters property.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.

Applies to

Product	Versions

Type.GetGenericParameterConstraints Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an array of Type objects that represent the constraints on the current generic type parameter.

C#

```
public virtual Type[] GetGenericParameterConstraints ();
```

Returns

Type[]

An array of Type objects that represent the constraints on the current generic type parameter.

Exceptions

InvalidOperationException

The current Type object is not a generic type parameter. That is, the IsGenericParameter property returns `false`.

Examples

The following code example defines a generic type `Test` with two type parameters that have different constraints. When the program executes, the constraints are examined using the GenericParameterAttributes property and the GetGenericParameterConstraints method.

C#

```
using System;
using System.Reflection;
```

```
// Define a sample interface to use as an interface constraint.
public interface ITest {}

// Define a base type to use as a base class constraint.
public class Base {}

// Define the generic type to examine. The first generic type parameter,
// T, derives from the class Base and implements ITest. This demonstrates
// a base class constraint and an interface constraint. The second generic
// type parameter, U, must be a reference type (class) and must have a
// default constructor (new()). This demonstrates special constraints.
//
public class Test<T,U>
    where T : Base, ITest
    where U : class, new() {}

// Define a type that derives from Base and implements ITest. This type
// satisfies the constraints on T in class Test.
public class Derived : Base, ITest {}

public class Example
{
    public static void Main()
    {
        // To get the generic type definition, omit the type
        // arguments but retain the comma to indicate the number
        // of type arguments.
        //
        Type def = typeof(Test<,>);
        Console.WriteLine("\r\nExamining generic type {0}", def);

        // Get the type parameters of the generic type definition,
        // and display them.
        //
        Type[] defparams = def.GetGenericArguments();
        foreach (Type tp in defparams)
        {
            Console.WriteLine("\r\nType parameter: {0}", tp.Name);
            Console.WriteLine("\t{0}",
                ListGenericParameterAttributes(tp));

            // List the base class and interface constraints. The
            // constraints are returned in no particular order. If
            // there are no class or interface constraints, an empty
            // array is returned.
            //
            Type[] tpConstraints = tp.GetGenericParameterConstraints();
            foreach (Type tpc in tpConstraints)
            {
                Console.WriteLine("\t{0}", tpc);
            }
        }
    }
```

```
    // List the variance and special constraint flags.
    //
    private static string ListGenericParameterAttributes(Type t)
    {
        string retval;
        GenericParameterAttributes gpa = t.GenericParameterAttributes;
        GenericParameterAttributes variance = gpa &
            GenericParameterAttributes.VarianceMask;

        // Select the variance flags.
        if (variance == GenericParameterAttributes.None)
        {
            retval = "No variance flag;";
        }
        else
        {
            if ((variance & GenericParameterAttributes.Covariant) != 0)
                retval = "Covariant;";
            else
                retval = "Contravariant;";
        }

        // Select
        GenericParameterAttributes constraints = gpa &
            GenericParameterAttributes.SpecialConstraintMask;

        if (constraints == GenericParameterAttributes.None)
        {
            retval += " No special constraints";
        }
        else
        {
            if ((constraints &
GenericParameterAttributes.ReferenceTypeConstraint) != 0)
                retval += " ReferenceTypeConstraint";
            if ((constraints &
GenericParameterAttributes.NotNullableValueTypeConstraint) != 0)
                retval += " NotNullableValueTypeConstraint";
            if ((constraints &
GenericParameterAttributes.DefaultConstructorConstraint) != 0)
                retval += " DefaultConstructorConstraint";
        }

        return retval;
    }
}
/* This example produces the following output:

Examining generic type Test`2[T,U]

Type parameter: T
        No variance flag; no special constraints.
        Base
        ITest
```

```
Type parameter: U
        No variance flag; ReferenceTypeConstraint
DefaultConstructorConstraint
 */
```

Remarks

Each constraint on a generic type parameter is expressed as a Type object. Use the IsClass property to determine whether a constraint is the base class constraint; if the property returns `false`, the constraint is an interface constraint. If a type parameter has no class constraint and no interface constraints, an empty array is returned.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.

Type.GetGenericTypeDefinition Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a Type object that represents a generic type definition from which the current generic type can be constructed.

```
C#
public virtual Type GetGenericTypeDefinition ();
```

Returns

Type

A Type object representing a generic type from which the current type can be constructed.

Exceptions

InvalidOperationException

The current type is not a generic type. That is, IsGenericType returns `false`.

NotSupportedException

The invoked method is not supported in the base class. Derived classes must provide an implementation.

Examples

The following code example creates an instance of a constructed type by using ordinary instance creation and then uses the GetType and GetGenericTypeDefinition methods to retrieve the constructed type and the generic type definition. This example uses the generic Dictionary<TKey,TValue> type; the constructed type represents a Dictionary<TKey,TValue> of `Test` objects with string keys.

```
C#
```

```
using System;
using System.Reflection;
using System.Collections.Generic;

public class Test
{
    public static void Main()
    {
        Console.WriteLine("\r\n--- Get the generic type that defines a
constructed type.");

        // Create a Dictionary of Test objects, using strings for the
        // keys.
        Dictionary<string, Test> d = new Dictionary<string, Test>();

        // Get a Type object representing the constructed type.
        //
        Type constructed = d.GetType();
        DisplayTypeInfo(constructed);

        Type generic = constructed.GetGenericTypeDefinition();
        DisplayTypeInfo(generic);
    }

    private static void DisplayTypeInfo(Type t)
    {
        Console.WriteLine("\r\n{0}", t);
        Console.WriteLine("\tIs this a generic type definition? {0}",
            t.IsGenericTypeDefinition);
        Console.WriteLine("\tIs it a generic type? {0}",
            t.IsGenericType);
        Type[] typeArguments = t.GetGenericArguments();
        Console.WriteLine("\tList type arguments ({0}):",
typeArguments.Length);
        foreach (Type tParam in typeArguments)
        {
            Console.WriteLine("\t\t{0}", tParam);
        }
    }
}

/* This example produces the following output:

--- Get the generic type that defines a constructed type.

System.Collections.Generic.Dictionary`2[System.String,Test]
        Is this a generic type definition? False
        Is it a generic type? True
        List type arguments (2):
                System.String
                Test

System.Collections.Generic.Dictionary`2[TKey,TValue]
        Is this a generic type definition? True
```

```
        Is it a generic type? True
        List type arguments (2):
                TKey
                TValue
 */
```

Remarks

A generic type definition is a template from which other types can be constructed. For example, from the generic type definition `G<T>` (expressed in C# syntax; `G(Of T)` in Visual Basic or `generic <typename T> ref class G` in C++) you can construct and instantiate the type `G<int>` (`G(Of Integer)` in Visual Basic). Given a Type object representing this constructed type, the GetGenericTypeDefinition method returns the generic type definition.

If two constructed types are created from the same generic type definition, using the same type arguments, the GetGenericTypeDefinition method returns the same Type object for both types.

If you call the GetGenericTypeDefinition method on a Type object that already represents a generic type definition, it returns the current Type.

> **Important**
>
> An array of generic types is not itself generic. In the C# code `A<int>[] v;` or the Visual Basic code `Dim v() As A(Of Integer)`, the type of variable `v` is not generic. Use **IsGenericType** to determine whether a type is generic before calling **GetGenericTypeDefinition**.

For a list of the invariant conditions for terms used in generic reflection, see the IsGenericType property remarks.

Type.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for this instance.

Examples

The following example displays the hash code of the `System.Windows.Forms.Button` class.

C#

```
using System;
using System.Security;
using System.Reflection;

class FieldsSample
{
    public static void Main()
    {
        Type myType = typeof(System.Net.IPAddress);
        FieldInfo [] myFields = myType.GetFields(BindingFlags.Static |
BindingFlags.NonPublic);
        Console.WriteLine ("\nThe IPAddress class has the following
nonpublic fields: ");
        foreach (FieldInfo myField in myFields)
        {
            Console.WriteLine(myField.ToString());
        }
        Type myType1 = typeof(System.Net.IPAddress);
        FieldInfo [] myFields1 = myType1.GetFields();
```

```
        Console.WriteLine ("\nThe IPAddress class has the following public
fields: ");
        foreach (FieldInfo myField in myFields1)
        {
            Console.WriteLine(myField.ToString());
        }
        try
        {
            Console.WriteLine("The HashCode of the
System.Windows.Forms.Button type is: {0}",
                typeof(System.Windows.Forms.Button).GetHashCode());
        }
        catch(SecurityException e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Message: "+e.Message);
        }
        catch(Exception e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Message: "+e.Message);
        }
    }
}
```

Remarks

This method overrides Object.GetHashCode.

Type.GetInterface Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific interface implemented or inherited by the current Type.

Overloads

Expand table

GetInterface(String)	Searches for the interface with the specified name.
GetInterface(String, Boolean)	When overridden in a derived class, searches for the specified interface, specifying whether to do a case-insensitive search for the interface name.

GetInterface(String)

Searches for the interface with the specified name.

C#

```
public Type? GetInterface (string name);
```

Parameters

`name` String

The string containing the name of the interface to get. For generic interfaces, this is the mangled name.

Returns

Type

An object representing the interface with the specified name, implemented or inherited by the current Type, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

AmbiguousMatchException

The current Type represents a type that implements the same generic interface with different type arguments.

Examples

The following code example uses the GetInterface(String) method to search the Hashtable class for the IDeserializationCallback interface, and lists the methods of the interface.

The code example also demonstrates the GetInterface(String, Boolean) method overload and the GetInterfaceMap method.

C#

```
public static void Main()
{
    Hashtable hashtableObj = new Hashtable();
    Type objType = hashtableObj.GetType();
    MethodInfo[] arrayMethodInfo;
    MemberInfo[] arrayMemberInfo;
    try
    {
        // Get the methods implemented in 'IDeserializationCallback'
interface.
        arrayMethodInfo
=objType.GetInterface("IDeserializationCallback").GetMethods();
        Console.WriteLine ("\nMethods of 'IDeserializationCallback'
Interface :");
        foreach(MethodInfo methodInfo in arrayMethodInfo)
            Console.WriteLine (methodInfo);

        // Get FullName for interface by using Ignore case search.
        Console.WriteLine ("\nMethods of 'IEnumerable' Interface");
        arrayMethodInfo =
objType.GetInterface("ienumerable",true).GetMethods();
        foreach(MethodInfo methodInfo in arrayMethodInfo)
           Console.WriteLine (methodInfo);

        //Get the Interface methods for 'IDictionary' interface
```

```
        InterfaceMapping interfaceMappingOb =
objType.GetInterfaceMap(typeof(IDictionary));
        arrayMemberInfo = interfaceMappingObj.InterfaceMethods;
        Console.WriteLine ("\nHashtable class Implements the following
IDictionary Interface methods :");
        foreach(MemberInfo memberInfo in arrayMemberInfo)
           Console.WriteLine (memberInfo);
    }
    catch (Exception e)
    {
        Console.WriteLine ("Exception : " + e.ToString());
    }
}
```

Remarks

The search for `name` is case-sensitive.

If the current Type represents a constructed generic type, this method returns the Type with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the interface constraints and any interfaces inherited from class or interface constraints.

> **Note**
>
> For generic interfaces, the `name` parameter is the mangled name, ending with a grave accent (`) and the number of type parameters. This is true for both generic interface definitions and constructed generic interfaces. For example, to find `IExample<T>` (`IExample(Of T)` in Visual Basic) or `IExample<string>` (`IExample(Of String)` in Visual Basic), search for `"IExample`1"`.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetInterface(String, Boolean)

When overridden in a derived class, searches for the specified interface, specifying whether to do a case-insensitive search for the interface name.

C#

```
public abstract Type? GetInterface (string name, bool ignoreCase);
```

Parameters

`name` String

The string containing the name of the interface to get. For generic interfaces, this is the mangled name.

`ignoreCase` Boolean

`true` to ignore the case of that part of `name` that specifies the simple interface name (the part that specifies the namespace must be correctly cased).

-or-

`false` to perform a case-sensitive search for all parts of `name`.

Returns

Type

An object representing the interface with the specified name, implemented or inherited by the current Type, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

AmbiguousMatchException

The current Type represents a type that implements the same generic interface with different type arguments.

Examples

The following code example uses the GetInterface(String, Boolean) method to perform a case-insensitive search of the Hashtable class for the IEnumerable interface.

The code example also demonstrates the GetInterface(String) method overload and the GetInterfaceMap method.

C#

```
public static void Main()
{
    Hashtable hashtableObj = new Hashtable();
    Type objType = hashtableObj.GetType();
    MethodInfo[] arrayMethodInfo;
    MemberInfo[] arrayMemberInfo;
    try
    {
        // Get the methods implemented in 'IDeserializationCallback'
interface.
        arrayMethodInfo
=objType.GetInterface("IDeserializationCallback").GetMethods();
        Console.WriteLine ("\nMethods of 'IDeserializationCallback'
Interface :");
        foreach(MethodInfo methodInfo in arrayMethodInfo)
            Console.WriteLine (methodInfo);

        // Get FullName for interface by using Ignore case search.
        Console.WriteLine ("\nMethods of 'IEnumerable' Interface");
        arrayMethodInfo =
objType.GetInterface("ienumerable",true).GetMethods();
        foreach(MethodInfo methodInfo in arrayMethodInfo)
           Console.WriteLine (methodInfo);

        //Get the Interface methods for 'IDictionary' interface
        InterfaceMapping interfaceMappingOb =
objType.GetInterfaceMap(typeof(IDictionary));
        arrayMemberInfo = interfaceMappingObj.InterfaceMethods;
        Console.WriteLine ("\nHashtable class Implements the following
IDictionary Interface methods :");
        foreach(MemberInfo memberInfo in arrayMemberInfo)
           Console.WriteLine (memberInfo);
    }
    catch (Exception e)
    {
```

```
        Console.WriteLine ("Exception : " + e.ToString());
    }
}
```

Remarks

The `ignoreCase` parameter applies only to the simple interface name, not to the namespace. The portion of `name` that specifies the namespace must have the correct case, or the interface will not be found. For example, the string "System.icomparable" finds the IComparable interface, but the string "system.icomparable" does not.

If the current Type represents a constructed generic type, this method returns the Type with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the interface constraints and any interfaces inherited from class or interface constraints.

> **Note**
>
> For generic interfaces, the `name` parameter is the mangled name, ending with a grave accent (`) and the number of type parameters. This is true for both generic interface definitions and constructed generic interfaces. For example, to find `IExample<T>` (`IExample(Of T)` in Visual Basic) or `IExample<string>` (`IExample(Of String)` in Visual Basic), search for `"IExample`1"`.

Type.GetInterfaceMap(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an interface mapping for the specified interface type.

C#

```
public virtual System.Reflection.InterfaceMapping GetInterfaceMap (Type
interfaceType);
```

Parameters

`interfaceType` Type

The interface type to retrieve a mapping for.

Returns

InterfaceMapping

An object that represents the interface mapping for `interfaceType`.

Exceptions

ArgumentException

`interfaceType` is not implemented by the current type.

-or-

The `interfaceType` argument does not refer to an interface.

-or-

The current instance or `interfaceType` argument is an open generic type; that is, the ContainsGenericParameters property returns `true`.

-or-

`interfaceType` is a generic interface, and the current type is an array type.

ArgumentNullException

`interfaceType` is `null`.

InvalidOperationException

The current Type represents a generic type parameter; that is, IsGenericParameter is `true`.

NotSupportedException

The invoked method is not supported in the base class. Derived classes must provide an implementation.

Examples

The following example calls the GetInterfaceMap method to determine how the IFormatProvider interface maps to CultureInfo methods, and how the IAppDomainSetup interface maps to AppDomainSetup properties. Note that, because the IAppDomainSetup interface defines a set of properties, the returned InterfaceMapping object includes separate MethodInfo objects for a property's get and set accessors.

C#

```
using System;
using System.Globalization;
using System.Reflection;

public class Example
{
   public static void Main()
   {
      Type[] interf = { typeof(IFormatProvider), typeof(IAppDomainSetup) };
      Type[] impl = { typeof(CultureInfo), typeof(AppDomainSetup) };

      for (int ctr = 0; ctr < interf.Length; ctr++)
         ShowInterfaceMapping(interf[ctr], impl[ctr]);
   }

   private static void ShowInterfaceMapping(Type intType, Type implType)
   {
      InterfaceMapping map = implType.GetInterfaceMap(intType);
      Console.WriteLine("Mapping of {0} to {1}: ", map.InterfaceType,
map.TargetType);
      for (int ctr = 0; ctr < map.InterfaceMethods.Length; ctr++) {
         MethodInfo im = map.InterfaceMethods[ctr];
         MethodInfo tm = map.TargetMethods[ctr];
         Console.WriteLine("   {0} --> {1}", im.Name,tm.Name);
```

```
        }
        Console.WriteLine();
    }
}
// The example displays the following output:
//    Mapping of System.IFormatProvider to System.Globalization.CultureInfo:
//       GetFormat --> GetFormat
//
//    Mapping of System.IAppDomainSetup to System.AppDomainSetup:
//       get_ApplicationBase --> get_ApplicationBase
//       set_ApplicationBase --> set_ApplicationBase
//       get_ApplicationName --> get_ApplicationName
//       set_ApplicationName --> set_ApplicationName
//       get_CachePath --> get_CachePath
//       set_CachePath --> set_CachePath
//       get_ConfigurationFile --> get_ConfigurationFile
//       set_ConfigurationFile --> set_ConfigurationFile
//       get_DynamicBase --> get_DynamicBase
//       set_DynamicBase --> set_DynamicBase
//       get_LicenseFile --> get_LicenseFile
//       set_LicenseFile --> set_LicenseFile
//       get_PrivateBinPath --> get_PrivateBinPath
//       set_PrivateBinPath --> set_PrivateBinPath
//       get_PrivateBinPathProbe --> get_PrivateBinPathProbe
//       set_PrivateBinPathProbe --> set_PrivateBinPathProbe
//       get_ShadowCopyDirectories --> get_ShadowCopyDirectories
//       set_ShadowCopyDirectories --> set_ShadowCopyDirectories
//       get_ShadowCopyFiles --> get_ShadowCopyFiles
//       set_ShadowCopyFiles --> set_ShadowCopyFiles
```

Remarks

The interface map denotes how an interface is mapped into the actual members on a class that implements that interface.

If the current Type represents a constructed generic type, type parameters are replaced by the appropriate type arguments in the elements of the InterfaceMapping returned by this method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.GetInterfaces Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, gets all the interfaces implemented or inherited by the current Type.

C#

```
public abstract Type[] GetInterfaces ();
```

Returns

Type[]

An array of Type objects representing all the interfaces implemented or inherited by the current Type.

-or-

An empty array of type Type, if no interfaces are implemented or inherited by the current Type.

Exceptions

TargetInvocationException

A static initializer is invoked and throws an exception.

Examples

The following example gets the type of the specified class and displays all the interfaces that the type implements or inherits. To compile the Visual Basic example, use the following compiler commands:

```
vbc type_getinterfaces1.vb /r:System.Web.dll /r:System.dll
```

C#

```
using System;
using System.Collections.Generic;

public class Example
{
    static void Main()
    {
        Console.WriteLine("\r\nInterfaces implemented by Dictionary<int,
string>:\r\n");

        foreach (Type tinterface in typeof(Dictionary<int,
string>).GetInterfaces())
        {
            Console.WriteLine(tinterface.ToString());
        }

        //Console.ReadLine()      // Uncomment this line for Visual Studio.
    }
}

/* This example produces output similar to the following:

Interfaces implemented by Dictionary<int, string>:

System.Collections.Generic.IDictionary`2[System.Int32,System.String]
System.Collections.Generic.ICollection`1[System.Collections.Generic.KeyValue
Pair`2[System.Int32,System.String]]
System.Collections.Generic.IEnumerable`1[System.Collections.Generic.KeyValue
Pair`2[System.Int32,System.String]]
System.Collection.IEnumerable
System.Collection.IDictionary
System.Collection.ICollection
System.Runtime.Serialization.ISerializable
System.Runtime.Serialization.IDeserializationCallback
 */
```

Remarks

In .NET 6 and earlier versions, the GetInterfaces method does not return interfaces in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which interfaces are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

If the current Type represents a constructed generic type, this method returns the Type objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the interface constraints and any interfaces

inherited from class or interface constraints.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.GetMember Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the specified members of the current Type.

Overloads

Expand table

GetMember(String)	Searches for the public members with the specified name.
GetMember(String, BindingFlags)	Searches for the specified members, using the specified binding constraints.
GetMember(String, MemberTypes, BindingFlags)	Searches for the specified members of the specified member type, using the specified binding constraints.

GetMember(String)

Searches for the public members with the specified name.

C#

```
public System.Reflection.MemberInfo[] GetMember (string name);
```

Parameters

name String

The string containing the name of the public members to get.

Returns

MemberInfo[]

An array of MemberInfo objects representing the public members with the specified name, if found; otherwise, an empty array.

Exceptions

ArgumentNullException

`name` is `null`.

Examples

The following example displays all the members of the `String` class that start with the letter C.

C#

```
using System;
using System.Security;
using System.Reflection;

public class MyMemberSample
{
    public static void Main()
    {
        MyMemberSample myClass = new MyMemberSample();
        try
        {
            myClass.GetMemberInfo();
            myClass.GetPublicStaticMemberInfo();
            myClass.GetPublicInstanceMethodMemberInfo();
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("ArgumentNullException occurred.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
        catch(NotSupportedException e)
        {
            Console.WriteLine("NotSupportedException occurred.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
        catch(SecurityException e)
        {
            Console.WriteLine("SecurityException occurred.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
        catch(Exception e)
```

```
        {
            Console.WriteLine("Exception occurred.");
            Console.WriteLine("Source: " + e.Source);
            Console.WriteLine("Message: " + e.Message);
        }
    }

    public void GetMemberInfo()
    {
        String myString = "GetMember_String";

        Type myType = myString.GetType();
        // Get the members for myString starting with the letter C.
        MemberInfo[] myMembers = myType.GetMember("C*");
        if(myMembers.Length > 0)
        {
            Console.WriteLine("\nThe member(s) starting with the letter C
for type {0}:", myType);
            for(int index=0; index < myMembers.Length; index++)
                Console.WriteLine("Member {0}: {1}", index + 1,
myMembers[index].ToString());
        }
        else
        {
            Console.WriteLine("No members match the search criteria.");
        }
    }
```

Remarks

The search for `name` is case-sensitive. The search includes public static and public instance members.

Members include properties, methods, fields, events, and so on.

In .NET 6 and earlier versions, the GetMember method does not return members in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which members are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

This method overload will not find class initializers (static constructor). To find class initializers, use an overload that takes BindingFlags, and specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the MemberInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the members of the class constraint, or the members of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text

name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetMember(String, BindingFlags)

Searches for the specified members, using the specified binding constraints.

C#

```
public virtual System.Reflection.MemberInfo[] GetMember (string name,
System.Reflection.BindingFlags bindingAttr);
```

Parameters

`name` String

The string containing the name of the members to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

MemberInfo[]

An array of MemberInfo objects representing the public members with the specified name, if found; otherwise, an empty array.

Implements

GetMember(String, BindingFlags)

Exceptions

ArgumentNullException

`name` is `null`.

Examples

The following example displays all the public static members of the `myString` class that start with the letter C.

C#

```
public void GetPublicStaticMemberInfo()
{
    String myString = "GetMember_String_BindingFlag";
    Type myType = myString.GetType();
    // Get the public static members for the class myString starting with
the letter C.
    MemberInfo[] myMembers = myType.GetMember("C*",
        BindingFlags.Public |BindingFlags.Static);
    if(myMembers.Length > 0)
    {
        Console.WriteLine("\nThe public static member(s) starting with
the letter C for type {0}:", myType);
        for(int index=0; index < myMembers.Length; index++)
            Console.WriteLine("Member {0}: {1}", index + 1,
myMembers[index].ToString());
    }
    else
```

```
    {
        Console.WriteLine("No members match the search criteria.");
    }
}
```

Remarks

This method can be overridden by a derived class.

Members include properties, methods, fields, events, and so on.

In .NET 6 and earlier versions, the GetMember method does not return members in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which members are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following BindingFlags filter flags can be used to define which members to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public members in the search.
- Specify `BindingFlags.NonPublic` to include non-public members (that is, private, internal, and protected members) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

See System.Reflection.BindingFlags for more information.

To get the class initializer (static constructor) using this method overload, you must specify "static constructor" for `name`, and BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual

Basic) for `bindingAttr`. You can also get the class initializer using the TypeInitializer property.

If the current Type represents a constructed generic type, this method returns the MemberInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the members of the class constraint, or the members of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

.NET Standard	2.0, 2.1

GetMember(String, MemberTypes, BindingFlags)

Searches for the specified members of the specified member type, using the specified binding constraints.

C#

```
public virtual System.Reflection.MemberInfo[] GetMember (string name, System.Reflection.MemberTypes type, System.Reflection.BindingFlags bindingAttr);
```

Parameters

`name` String

The string containing the name of the members to get.

`type` MemberTypes

The value to search for.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

MemberInfo[]

An array of MemberInfo objects representing the public members with the specified name, if found; otherwise, an empty array.

Exceptions

ArgumentNullException

`name` is `null`.

NotSupportedException

A derived class must provide an implementation.

Examples

The following example displays all the methods of the `myString` class that start with the letter C.

C#

```
    public void GetPublicInstanceMethodMemberInfo()
    {
        String myString = "GetMember_String_MemberType_BindingFlag";
        Type myType = myString.GetType();
        // Get the public instance methods for myString starting with the
letter C.
        MemberInfo[] myMembers = myType.GetMember("C*",
MemberTypes.Method,
            BindingFlags.Public | BindingFlags.Instance);
        if(myMembers.Length > 0)
        {
            Console.WriteLine("\nThe public instance method(s) starting
with the letter C for type {0}:", myType);
            for(int index=0; index < myMembers.Length; index++)
                Console.WriteLine("Member {0}: {1}", index + 1,
myMembers[index].ToString());
        }
        else
        {
            Console.WriteLine("No members match the search criteria.");
        }
    }
}
```

Remarks

Members include properties, methods, fields, events, and so on.

In .NET 6 and earlier versions, the GetMember method does not return members in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which members are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following BindingFlags filter flags can be used to define which members to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.

- Specify `BindingFlags.Public` to include public members in the search.
- Specify `BindingFlags.NonPublic` to include non-public members (that is, private, internal, and protected members) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

See System.Reflection.BindingFlags for more information.

To get the class initializer (static constructor) using this method overload, you must specify "static constructor" for `name`, MemberTypes.Constructor for `type`, and BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic) for `bindingAttr`. You can also get the class initializer using the TypeInitializer property.

If the current Type represents a constructed generic type, this method returns the MemberInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the members of the class constraint, or the members of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

Type.GetMembers Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the members (properties, methods, fields, events, and so on) of the current Type.

Overloads

Expand table

GetMembers(BindingFlags)	When overridden in a derived class, searches for the members defined for the current Type, using the specified binding constraints.
GetMembers()	Returns all the public members of the current Type.

GetMembers(BindingFlags)

When overridden in a derived class, searches for the members defined for the current Type, using the specified binding constraints.

C#

```
public abstract System.Reflection.MemberInfo[] GetMembers
(System.Reflection.BindingFlags bindingAttr);
```

Parameters

bindingAttr BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

MemberInfo[]

An array of MemberInfo objects representing all members defined for the current Type that match the specified binding constraints.

-or-

An empty array if no members are defined for the current Type, or if none of the defined members match the binding constraints.

Implements

GetMembers(BindingFlags)

Examples

The following code example demonstrates how to use the GetMembers(BindingFlags) method overload to collect information about all public instance members of a specified class.

C#

```
class MyClass
{
   public int myInt = 0;
   public string myString = null;

   public MyClass()
   {
   }
   public void Myfunction()
   {
   }
}

class Type_GetMembers_BindingFlags
{
   public static void Main()
   {
      try
      {
         MyClass MyObject = new MyClass();
         MemberInfo [] myMemberInfo;

         // Get the type of the class 'MyClass'.
         Type myType = MyObject.GetType();
```

```
         // Get the public instance members of the class 'MyClass'.
         myMemberInfo =
myType.GetMembers(BindingFlags.Public|BindingFlags.Instance);

         Console.WriteLine( "\nThe public instance members of class '{0}'
are : \n", myType);
         for (int i =0 ; i < myMemberInfo.Length ; i++)
         {
            // Display name and type of the member of 'MyClass'.
            Console.WriteLine( "'{0}' is a {1}", myMemberInfo[i].Name,
myMemberInfo[i].MemberType);
         }
      }
      catch (SecurityException e)
      {
         Console.WriteLine("SecurityException : " + e.Message );
      }

      //Output:
      //The public instance members of class 'MyClass' are :

      //'Myfunction' is a Method
      //'ToString' is a Method
      //'Equals' is a Method
      //'GetHashCode' is a Method
      //'GetType' is a Method
      //'.ctor' is a Constructor
      //'myInt' is a Field
      //'myString' is a Field
   }
}
```

Remarks

Members include properties, methods, constructors, fields, events, and nested types.

For the `GetMethods(BindingFlags)` overload to successfully retrieve method information, the `bindingAttr` argument must include at least one of BindingFlags.Instance and BindingFlags.Static, along with at least one of BindingFlags.NonPublic and BindingFlags.Public. The sole exception is a method call with BindingFlags.NonPublic, which returns member information about nested types.

The following BindingFlags filter flags can be used to define which members to include in the search:

- Specify `BindingFlags.Instance` to include instance methods.
- Specify `BindingFlags.Static` to include static methods.

- Specify `BindingFlags.Public` to include public methods in the search.
- Specify `BindingFlags.NonPublic` to include non-public methods (that is, private, internal, and protected methods) in the search. Only protected and internal methods on base classes are returned; private methods on base classes are not returned.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.
- Specify `BindingFlags.Default` alone to return an empty MethodInfo array.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

See System.Reflection.BindingFlags for more information.

In .NET 6 and earlier versions, the GetMembers method does not return members in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which members are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

To get the class initializer (static constructor) using this method overload, you must specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

If the current Type represents a constructed generic type, this method returns the MemberInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the members of the class constraint, or the members of Object if there is no class constraint.

.NET Standard	2.0, 2.1

GetMembers()

Returns all the public members of the current Type.

C#

```
public System.Reflection.MemberInfo[] GetMembers ();
```

Returns

MemberInfo[]

An array of MemberInfo objects representing all the public members of the current Type.

-or-

An empty array of type MemberInfo, if the current Type does not have public members.

Examples

The following code example demonstrates how to use the GetMembers() method overload to collect information about all public members of a specified class.

C#

```
class MyClass
{
   public int myInt = 0;
   public string myString = null;

   public MyClass()
   {
   }
   public void Myfunction()
   {
   }
}

class Type_GetMembers
{
   public static void Main()
   {
      try
      {
         MyClass myObject = new MyClass();
         MemberInfo[] myMemberInfo;

         // Get the type of 'MyClass'.
         Type myType = myObject.GetType();

         // Get the information related to all public member's of
'MyClass'.
         myMemberInfo = myType.GetMembers();

         Console.WriteLine( "\nThe members of class '{0}' are :\n",
myType);
         for (int i =0 ; i < myMemberInfo.Length ; i++)
         {
            // Display name and type of the concerned member.
            Console.WriteLine( "'{0}' is a {1}", myMemberInfo[i].Name,
myMemberInfo[i].MemberType);
         }
      }
      catch(SecurityException e)
      {
         Console.WriteLine("Exception : " + e.Message );
      }
   }
}
```

Remarks

Members include properties, methods, constructors, fields, events, and nested types.

In .NET 6 and earlier versions, the GetMembers method does not return members in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which members are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

This method overload calls the GetMembers(BindingFlags) method overload, with BindingFlags.Public | BindingFlags.Instance | BindingFlags.Static (BindingFlags.Public `Or` BindingFlags.Instance `Or` BindingFlags.Static in Visual Basic). It will not find class initializers (static constructors). To find class initializers, call the GetMembers(BindingFlags) overload, and specify BindingFlags.Static | BindingFlags.NonPublic (BindingFlags.Static `Or` BindingFlags.NonPublic in Visual Basic). You can also get the class initializer using the TypeInitializer property.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the MemberInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the members of the class constraint, or the members of Object if there is no class constraint.

Type.GetMemberWithSameMetadataDefinitionAs(MemberInfo) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Searches for the MemberInfo on the current Type that matches the specified MemberInfo.

C#

```
public virtual System.Reflection.MemberInfo
GetMemberWithSameMetadataDefinitionAs (System.Reflection.MemberInfo member);
```

Parameters

member MemberInfo

The MemberInfo to find on the current Type.

Returns

MemberInfo

An object representing the member on the current Type that matches the specified member.

Exceptions

ArgumentNullException

`member` is `null`.

ArgumentException

`member` does not match a member on the current Type.

Remarks

This method can be used to find a constructed generic member given a member from a generic type definition.

Applies to

Product	Versions
.NET	6, 7, 8, 9

Type.GetMethod Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific method of the current Type.

Overloads

Expand table

GetMethod(String, Int32, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethod(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethod(String, Int32, BindingFlags, Binder, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints.
GetMethod(String, BindingFlags, Binder, Type[], ParameterModifier[])	Searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints.
GetMethod(String, Int32, Type[], ParameterModifier[])	Searches for the specified public method whose parameters match the specified generic parameter count, argument types and modifiers.
GetMethod(String, BindingFlags)	Searches for the specified method, using the specified binding constraints.
GetMethod(String, BindingFlags, Type[])	Searches for the specified method whose parameters match the specified argument types, using the specified binding constraints.

GetMethod(String, Int32, Type[])	Searches for the specified public method whose parameters match the specified generic parameter count and argument types.
GetMethod(String, Type[])	Searches for the specified public method whose parameters match the specified argument types.
GetMethod(String)	Searches for the public method with the specified name.
GetMethod(String, Type[], ParameterModifier[])	Searches for the specified public method whose parameters match the specified argument types and modifiers.

GetMethod(String, Int32, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])

Searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints and the specified calling convention.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name, int
genericParameterCount, System.Reflection.BindingFlags bindingAttr,
System.Reflection.Binder? binder, System.Reflection.CallingConventions
callConvention, Type[] types, System.Reflection.ParameterModifier[]?
modifiers);
```

Parameters

name String

The string containing the name of the public method to get.

genericParameterCount Int32

The number of generic type parameters of the method.

bindingAttr BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`callConvention` CallingConventions

The object that specifies the set of rules to use regarding the order and layout of arguments, how the return value is passed, what registers are used for arguments, and how the stack is cleaned up.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. To be only used when calling through COM interop, and only parameters that are passed by reference are handled. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the method that matches the specified generic parameter count, argument types, modifiers, binding constraints and calling convention, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in the `types` array is `null`.

ArgumentException

`genericParameterCount` is negative.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

GetMethod(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])

Searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, System.Reflection.CallingConventions callConvention, Type[]
types, System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

name String

The string containing the name of the method to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`callConvention` CallingConventions

The object that specifies the set of rules to use regarding the order and layout of arguments, how the return value is passed, what registers are used for arguments, and how the stack is cleaned up.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. To be only used when calling through COM interop, and only parameters that are passed by reference are handled. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the method that matches the specified requirements, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one method is found with the specified name and matching the specified binding constraints.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

Examples

The following example finds specific overloads of `MethodA`, specifying binding constraints, calling conventions, and a variety of argument types.

> **Note**
>
> The Visual C# 2005 example requires the `/unsafe` compiler option.

C#

```
using System;
using System.Reflection;

class Program3
{
    // Methods to get:

    public void MethodA(int i, int j) { }
```

```
    public void MethodA(int[] i) { }

    public unsafe void MethodA(int* i) { }

    public void MethodA(ref int r) {}

    // Method that takes an out parameter:
    public void MethodA(int i, out int o) { o = 100;}

  static void Main(string[] args)
  {
    MethodInfo mInfo;

    // Get MethodA(int i, int j)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        CallingConventions.Any,
        new Type[] { typeof(int), typeof(int) },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int[] i)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        CallingConventions.Any,
        new Type[] { typeof(int[]) },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int* i)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        CallingConventions.Any,
        new Type[] { typeof(int).MakePointerType() },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(ref int r)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        CallingConventions.Any,
        new Type[] { typeof(int).MakeByRefType() },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int i, out int o)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        CallingConventions.Any,
        new Type[] { typeof(int), typeof(int).MakeByRefType() },
```

```
            null);
        Console.WriteLine("Found method: {0}", mInfo);
    }
}
```

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

The following table shows what members of a base class are returned by the `GetXXX` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the

derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

The following BindingFlags filter flags can be used to define which methods to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public methods in the search.
- Specify `BindingFlags.NonPublic` to include nonpublic methods (that is, private, internal, and protected methods) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the methods declared on the Type, not methods that were simply inherited.

See System.Reflection.BindingFlags for more information.

> ⓘ **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the MethodInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

> ⓘ **Note**

For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

.NET Standard	2.0, 2.1

GetMethod(String, Int32, BindingFlags, Binder, Type[], ParameterModifier[])

Searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name, int
genericParameterCount, System.Reflection.BindingFlags bindingAttr,
System.Reflection.Binder? binder, Type[] types,
System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`name` String

The string containing the name of the public method to get.

`genericParameterCount` Int32

The number of generic type parameters of the method.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. To be only used when calling through

COM interop, and only parameters that are passed by reference are handled. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the method that matches the specified generic parameter count, argument types, modifiers and binding constraints, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in the `types` array is `null`.

ArgumentException

`genericParameterCount` is negative.

Examples

The following example finds specific overloads of `MethodA`, specifying binding constraints and a variety of argument types.

> **Note**
>
> The Visual C# 2005 example requires the `/unsafe` compiler option.

C#

```
using System;
using System.Reflection;

class Program5
{
    // Methods to get:

    public void MethodA(int i, int j) { }

    public void MethodA(int[] i) { }

    public unsafe void MethodA(int* i) { }

    public void MethodA(ref int r) {}

    // Method that takes an out parameter.
    public void MethodA(int i, out int o) { o = 100; }

  static void Main(string[] args)
  {
    MethodInfo mInfo;

    // Get MethodA(int i, int j)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        new Type[] { typeof(int), typeof(int) },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int[] i)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        new Type[] { typeof(int[]) },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int* i)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        new Type[] { typeof(int).MakePointerType() },
        null);
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(ref int r)
    mInfo = typeof(Program).GetMethod("MethodA",
        BindingFlags.Public | BindingFlags.Instance,
        null,
        new Type[] { typeof(int).MakeByRefType() },
```

```
            null);
        Console.WriteLine("Found method: {0}", mInfo);

        // Get MethodA(int i, out int o)
        mInfo = typeof(Program).GetMethod("MethodA",
            BindingFlags.Public | BindingFlags.Instance,
            null,
            new Type[] { typeof(int), typeof(int).MakeByRefType() },
            null);
        Console.WriteLine("Found method: {0}", mInfo);
    }
}
```

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

The following BindingFlags filter flags can be used to define which methods to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public methods in the search.
- Specify `BindingFlags.NonPublic` to include nonpublic methods (that is, private, internal, and protected methods) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the methods declared on the Type, not methods that were simply inherited.

See System.Reflection.BindingFlags for more information.

> **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the MethodInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

GetMethod(String, Int32, Type[], ParameterModifier[])

Searches for the specified public method whose parameters match the specified generic parameter count, argument types and modifiers.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name, int
genericParameterCount, Type[] types,
System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`name` String

The string containing the name of the public method to get.

`genericParameterCount` Int32

The number of generic type parameters of the method.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. To be only used when calling through COM interop, and only parameters that are passed by reference are handled. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the public method that matches the specified generic parameter count, argument types and modifiers, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in the `types` array is `null`.

ArgumentException

`genericParameterCount` is negative.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

GetMethod(String, BindingFlags)

Searches for the specified method, using the specified binding constraints.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name,
System.Reflection.BindingFlags bindingAttr);
```

Parameters

`name` String

The string containing the name of the method to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

Returns

MethodInfo

An object representing the method that matches the specified requirements, if found; otherwise, `null`.

Implements

GetMethod(String, BindingFlags)

Exceptions

AmbiguousMatchException

More than one method is found with the specified name and matching the specified binding constraints.

ArgumentNullException

`name` is `null`.

Examples

The following example gets the method that matches the specified binding flags.

C#

```
using System;
using System.Reflection;

class Program2
{
```

```
    // Method to get:
    public void MethodA() { }

    static void Main(string[] args)
    {

        // Get MethodA()
        MethodInfo mInfo = typeof(Program).GetMethod("MethodA",
            BindingFlags.Public | BindingFlags.Instance);
        Console.WriteLine("Found method: {0}", mInfo);
    }
}
```

Remarks

The following BindingFlags filter flags can be used to define which methods to include in the search:

- You must specify either BindingFlags.Instance or BindingFlags.Static in order to get a return.
- Specify BindingFlags.Public to include public methods in the search.
- Specify BindingFlags.NonPublic to include non-public methods (that is, private, internal, and protected methods) in the search.
- Specify BindingFlags.FlattenHierarchy to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- BindingFlags.IgnoreCase to ignore the case of `name`.
- BindingFlags.DeclaredOnly to search only the methods declared on the Type, not methods that were simply inherited.

See System.Reflection.BindingFlags for more information.

If a method is overloaded and more than one overload meets the constraints specified by the `bindingAttr` argument, the method throws an AmbiguousMatchException exception. In the following example, an exception is thrown because:

- The `TestClass` type has two public instance overloads of the `DisplayValue` method, `DisplayValue(String)` and `DisplayValue(String, Object[])`.
- The `TestClass` type has two public instance overloads of the `Equals` method, one of which is inherited from Object: `Equals(TestClass)` and `Equals(Object)`.

C#

```
using System;
using System.Reflection;

public class TestClass
{
    public void DisplayValue(String s)
    {
        Console.WriteLine(s);
    }

    public void DisplayValue(String s, params Object[] values)
    {
        Console.WriteLine(s, values);
    }

    public static bool Equals(TestClass t1, TestClass t2)
    {
        return Object.ReferenceEquals(t1, t2);
    }

    public bool Equals(TestClass t)
    {
        return Object.ReferenceEquals(this, t);
    }
}

public class Example1
{
    public static void Main()
    {
        Type t = typeof(TestClass);

        RetrieveMethod(t, "DisplayValue", BindingFlags.Public |
BindingFlags.Instance);

        RetrieveMethod(t, "Equals", BindingFlags.Public |
BindingFlags.Instance);

        RetrieveMethod(t, "Equals", BindingFlags.Public |
BindingFlags.Instance | BindingFlags.DeclaredOnly);

        RetrieveMethod(t, "Equals", BindingFlags.Public |
BindingFlags.Static);
    }
```

```
    private static void RetrieveMethod(Type t, String name, BindingFlags
flags)
    {
        try
        {
            MethodInfo m = t.GetMethod(name, flags);
            if (m != null)
            {
                Console.Write("{0}.{1}(", t.Name, m.Name);
                ParameterInfo[] parms = m.GetParameters();
                for (int ctr = 0; ctr < parms.Length; ctr++)
                {
                    Console.Write(parms[ctr].ParameterType.Name);
                    if (ctr < parms.Length - 1)
                        Console.Write(", ");
                }
                Console.WriteLine(")");
            }
            else
            {
                Console.WriteLine("Method not found");
            }
        }
        catch (AmbiguousMatchException)
        {
            Console.WriteLine("The following duplicate matches were
found:");
            MethodInfo[] methods = t.GetMethods(flags);
            foreach (var method in methods)
            {
                if (method.Name != name) continue;

                Console.Write("   {0}.{1}(", t.Name, method.Name);
                ParameterInfo[] parms = method.GetParameters();
                for (int ctr = 0; ctr < parms.Length; ctr++)
                {
                    Console.Write(parms[ctr].ParameterType.Name);
                    if (ctr < parms.Length - 1)
                        Console.Write(", ");
                }
                Console.WriteLine(")");
            }
        }
        Console.WriteLine();
    }
}
// The example displays the following output:
//       The following duplicate matches were found:
//          TestClass.DisplayValue(String)
//          TestClass.DisplayValue(String, Object[])
//
//       The following duplicate matches were found:
//          TestClass.Equals(TestClass)
//          TestClass.Equals(Object)
//
```

```
//       TestClass.Equals(TestClass)
//
//       TestClass.Equals(TestClass, TestClass)
```

You can do one of the following to retrieve a specific method:

- Change the binding constraints. In the previous example, attempting to retrieve a public instance `Equals` method that is declared by the type and not inherited successfully retrieves `Equals(TestClass)`.
- Call an overload of the GetMethod method that includes a `types` parameter which defines the types of the method's parameters.
- Call the GetMethods(BindingFlags) method to retrieve an array containing all of the methods belonging to a type that have the specified binding attributes. You can then iterate it to identify the duplicate methods named `name`. This approach is illustrated in the previous example's handler for the AmbiguousMatchException exception.

If the current Type represents a constructed generic type, this method returns the MethodInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetMethod(String, BindingFlags, Type[])

Searches for the specified method whose parameters match the specified argument types, using the specified binding constraints.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name,
System.Reflection.BindingFlags bindingAttr, Type[] types);
```

Parameters

`name` String

The string containing the name of the method to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted. -or- Default to return `null`.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get. -or- An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

Returns

MethodInfo

An object representing the method that matches the specified requirements, if found; otherwise, `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

GetMethod(String, Int32, Type[])

Searches for the specified public method whose parameters match the specified generic parameter count and argument types.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name, int
genericParameterCount, Type[] types);
```

Parameters

`name` String

The string containing the name of the public method to get.

`genericParameterCount` Int32

The number of generic type parameters of the method.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

Returns

MethodInfo

An object representing the public method whose parameters match the specified generic parameter count and argument types, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in the `types` array is `null`.

ArgumentException

`genericParameterCount` is negative.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

GetMethod(String, Type[])

Searches for the specified public method whose parameters match the specified argument types.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name, Type[]
types);
```

Parameters

name String

The string containing the name of the public method to get.

types Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

Returns

MethodInfo

An object representing the public method whose parameters match the specified argument types, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one method is found with the specified name and specified parameters.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

Examples

The following example finds specific overloads of `MethodA`, specifying a variety of argument types.

ⓘ **Note**

The Visual C# 2005 example requires the `/unsafe` compiler option.

C#

```
using System;
using System.Reflection;

class Program4
{
    // Methods to get:

    public void MethodA(int i, int j) { }

    public void MethodA(int[] i) { }

    public unsafe void MethodA(int* i) { }

    public void MethodA(ref int r) {}

    // Method that takes an out parameter:
    public void MethodA(int i, out int o) { o = 100;}

  static void Main(string[] args)
  {
    MethodInfo mInfo;

    // Get MethodA(int i, int i)
    mInfo = typeof(Program).GetMethod("MethodA",
        new Type[] { typeof(int), typeof(int) });
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int[] i)
    mInfo = typeof(Program).GetMethod("MethodA",
        new Type[] { typeof(int[]) });
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int* i)
    mInfo = typeof(Program).GetMethod("MethodA",
        new Type[] { typeof(int).MakePointerType() });
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(ref int r)
    mInfo = typeof(Program).GetMethod("MethodA",
        new Type[] { typeof(int).MakeByRefType() });
    Console.WriteLine("Found method: {0}", mInfo);

    // Get MethodA(int i, out int o)
    mInfo = typeof(Program).GetMethod("MethodA",
        new Type[] { typeof(int), typeof(int).MakeByRefType() });
    Console.WriteLine("Found method: {0}", mInfo);
```

```
    }
  }
```

The following example retrieves MethodInfo objects that represent the `Add` methods of a non-generic type (the ArrayList class), an open generic type (the List<T> class), and a closed generic type (the `List(Of String)` type.

C#

```
using System;
using System.Collections;
using System.Collections.Generic;
using System.Reflection;

public class Example
{
   public static void Main()
   {
      // Get a Type object that represents a non-generic type.
      GetAddMethod(typeof(ArrayList));

      var list = new List<String>();
      // Get a Type object that represents a constructed generic type.
      Type closed = list.GetType();
      GetAddMethod(closed);

      // Get a Type object that represents an open generic type.
      Type open = typeof(List<>);
      GetAddMethod(open);
   }

   private static void GetAddMethod(Type typ)
   {
      MethodInfo method;
      // Determine if this is a generic type.
      if (typ.IsGenericType) {
         // Is it an open generic type?
         if (typ.ContainsGenericParameters)
            method = typ.GetMethod("Add", typ.GetGenericArguments());
         // Get closed generic type arguments.
         else
            method = typ.GetMethod("Add", typ.GenericTypeArguments);
      }
      // This is not a generic type.
      else {
         method = typ.GetMethod("Add", new Type[] { typeof(Object) } );
      }

      // Test if an Add method was found.
      if (method == null) {
         Console.WriteLine("No Add method found.");
         return;
```

```
        }

        Type t = method.ReflectedType;
        Console.Write("{0}.{1}.{2}(", t.Namespace, t.Name, method.Name);
        ParameterInfo[] parms = method.GetParameters();
        for (int ctr = 0; ctr < parms.Length; ctr++)
           Console.Write("{0}{1}", parms[ctr].ParameterType.Name,
                         ctr < parms.Length - 1 ? ", " : "");

        Console.WriteLine(")");
    }
}
// The example displays the following output:
//       System.Collections.ArrayList.Add(Object)
//       System.Collections.Generic.List`1.Add(String)
//       System.Collections.Generic.List`1.Add(T)
```

The example defines a `GetAddMethod` method that retrieves the appropriate MethodInfo object. To provide the `types` argument for an open generic type, it calls the Type.GetGenericArguments method. To provide the `types` argument for a closed generic type, it retrieves the value of the Type.GenericTypeArguments property.

Remarks

The search for `name` is case-sensitive. The search includes public static and public instance methods.

> **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the MethodInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

> **Note**
>
> The `name` parameter cannot include type arguments. For example, the C# code `GetMethod("MyGenericMethod<int>")` searches for a method with the text name "`MyGenericMethod<int>`", rather than for a method named `MyGenericMethod` that

has one generic argument of type `int`. Instead, use `GetMethod("MyGenericMethod")` with the appropriate parameter in the `types` array.

See also

- MethodInfo

- GetMethodImpl(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])
- GetMethods()

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetMethod(String)

Searches for the public method with the specified name.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name);
```

Parameters

name String

The string containing the name of the public method to get.

Returns

MethodInfo

An object that represents the public method with the specified name, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one method is found with the specified name.

ArgumentNullException

`name` is `null`.

Examples

The following example gets a method named `MethodA`.

C#

```
using System;
using System.Reflection;

class Program
{

    // Method to get:
    public void MethodA() { }

    static void Main(string[] args)
    {

        // Get MethodA()
        MethodInfo mInfo = typeof(Program).GetMethod("MethodA");
        Console.WriteLine("Found method: {0}", mInfo);
    }
}
```

Remarks

The search for `name` is case-sensitive. The search includes public static and public instance methods.

If a method is overloaded and has more than one public method, the GetMethod(String) method throws an AmbiguousMatchException exception. In the following example, an exception is thrown because there is more than one public overload of the Int32.ToString method. On the other hand, because the

`Person.ToString` method overrides Object.ToString and therefore is not overloaded, the GetMethod(String) method is able to retrieve the MethodInfo object.

C#

```
using System;
using System.Reflection;

public class Person
{
    public String FirstName;
    public String LastName;

    public override String ToString()
    {
        return (FirstName + " " + LastName).Trim();
    }
}

public class Example2
{
    public static void Main()
    {
        Type t = typeof(Person);
        RetrieveMethod(t, "ToString");

        t = typeof(Int32);
        RetrieveMethod(t, "ToString");
    }

    private static void RetrieveMethod(Type t, String name)
    {
        try
        {
            MethodInfo m = t.GetMethod(name);
            if (m != null)
                Console.WriteLine("{0}.{1}: {2} method",
m.ReflectedType.Name,
                                  m.Name, m.IsStatic ? "Static" :
"Instance");
            else
                Console.WriteLine("{0}.ToString method not found",
t.Name);
        }
        catch (AmbiguousMatchException)
        {
            Console.WriteLine("{0}.{1} has multiple public overloads.",
                              t.Name, name);
        }
    }
}
// The example displays the following output:
```

```
//       Person.ToString: Instance method
//       Int32.ToString has multiple public overloads.
```

You can do one of the following to retrieve a specific method:

- Call the GetMethod(String, BindingFlags) method and specify a `bindingAttr` argument that uniquely identifies the method. For example, if the exception is thrown because a type has a static and an instance overload, you can specify a `bindingAttr` argument of BindingFlags.Instance `Or` BindingFlags.Instance.
- Call an overload of the GetMethod method that includes a `types` parameter which defines the types of the method's parameters.
- Call the GetMethods() method to retrieve an array containing all of the public methods belonging to a type. You can then iterate it to identify the duplicate methods named `name`.

If the current Type represents a constructed generic type, this method returns the MethodInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMember("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`.

.NET Standard	2.0, 2.1

GetMethod(String, Type[], ParameterModifier[])

Searches for the specified public method whose parameters match the specified argument types and modifiers.

C#

```
public System.Reflection.MethodInfo? GetMethod (string name, Type[]
types, System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`name` String

The string containing the name of the public method to get.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of Type objects (as provided by the EmptyTypes field) to get a method that takes no parameters.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. To be only used when calling through COM interop, and only parameters that are passed by reference are handled. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the public method that matches the specified requirements, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one method is found with the specified name and specified parameters.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

The search for `name` is case-sensitive. The search includes public static and public instance methods.

> **Note**

You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the MethodInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

> **Note**
>
> For generic methods, do not include the type arguments in `name`. For example, the C# code `GetMethod("MyMethod<int>")` searches for a member with the text name "`MyMethod<int>`", rather than for a method named `MyMethod` that has one generic argument of type `int`. Instead, use `GetMethod("MyMethod")` with the appropriate parameter in the `types` array.

Type.GetMethodImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

GetMethodImpl(String, Int32, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	When overridden in a derived class, searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints and the specified calling convention.
GetMethodImpl(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])	When overridden in a derived class, searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.

GetMethodImpl(String, Int32, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])

When overridden in a derived class, searches for the specified method whose parameters match the specified generic parameter count, argument types and modifiers, using the specified binding constraints and the specified calling convention.

C#

```
protected virtual System.Reflection.MethodInfo? GetMethodImpl (string
name, int genericParameterCount, System.Reflection.BindingFlags
bindingAttr, System.Reflection.Binder? binder,
System.Reflection.CallingConventions callConvention, Type[]? types,
System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`name` String

The string containing the name of the method to get.

`genericParameterCount` Int32

The number of generic type parameters of the method.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`callConvention` CallingConventions

The object that specifies the set of rules to use regarding the order and layout of arguments, how the return value is passed, what registers are used for arguments, and what process cleans up the stack.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a method that takes no parameters.

-or-

`null`. If `types` is `null`, arguments are not matched.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the method that matches the specified generic parameter count, argument types, modifiers, binding constraints and calling convention, if found; otherwise, `null`.

Exceptions

NotSupportedException

The method needs to be overriden and called in a derived class.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

GetMethodImpl(String, BindingFlags, Binder, CallingConventions, Type[], ParameterModifier[])

When overridden in a derived class, searches for the specified method whose parameters match the specified argument types and modifiers, using the specified binding constraints and the specified calling convention.

C#

```
protected abstract System.Reflection.MethodInfo? GetMethodImpl (string
name, System.Reflection.BindingFlags bindingAttr,
System.Reflection.Binder? binder, System.Reflection.CallingConventions
```

```
callConvention, Type[]? types, System.Reflection.ParameterModifier[]?
modifiers);
```

Parameters

`name` String

The string containing the name of the method to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`callConvention` CallingConventions

The object that specifies the set of rules to use regarding the order and layout of arguments, how the return value is passed, what registers are used for arguments, and what process cleans up the stack.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the method to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a method that takes no parameters.

-or-

`null`. If `types` is `null`, arguments are not matched.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

MethodInfo

An object representing the method that matches the specified requirements, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one method is found with the specified name and matching the specified binding constraints.

ArgumentNullException

`name` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

NotSupportedException

The current type is a TypeBuilder or GenericTypeParameterBuilder.

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

If `types` is `null`, arguments are not matched.

The following BindingFlags filter flags can be used to define which methods to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public methods in the search.
- Specify `BindingFlags.NonPublic` to include non-public methods (that is, private, internal, and protected methods) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the methods declared on the Type, not methods that were simply inherited.

See System.Reflection.BindingFlags for more information.

Type.GetMethods Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the methods of the current Type.

Overloads

Expand table

GetMethods(BindingFlags)	When overridden in a derived class, searches for the methods defined for the current Type, using the specified binding constraints.
GetMethods()	Returns all the public methods of the current Type.

GetMethods(BindingFlags)

When overridden in a derived class, searches for the methods defined for the current Type, using the specified binding constraints.

C#

```
public abstract System.Reflection.MethodInfo[] GetMethods
(System.Reflection.BindingFlags bindingAttr);
```

Parameters

bindingAttr BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

MethodInfo[]

An array of MethodInfo objects representing all methods defined for the current Type that match the specified binding constraints.

-or-

An empty array of type MethodInfo, if no methods are defined for the current Type, or if none of the defined methods match the binding constraints.

Implements

GetMethods(BindingFlags)

Examples

The following example creates a class with two public methods and one protected method, creates a `Type` object corresponding to `MyTypeClass`, gets all public and non-public methods, and displays their names.

C#

```
using System;
using System.Reflection;
using System.Reflection.Emit;

        // Create a class having two public methods and one protected
method.
public class MyTypeClass
{
    public void MyMethods()
    {
    }
    public int MyMethods1()
    {
        return 3;
    }
    protected String MyMethods2()
    {
        return "hello";
    }
}
public class TypeMain
{
    public static void Main()
    {
```

```
        Type myType =(typeof(MyTypeClass));
        // Get the public methods.
        MethodInfo[] myArrayMethodInfo =
myType.GetMethods(BindingFlags.Public|BindingFlags.Instance|BindingFlags.
DeclaredOnly);
        Console.WriteLine("\nThe number of public methods is {0}.",
myArrayMethodInfo.Length);
        // Display all the methods.
        DisplayMethodInfo(myArrayMethodInfo);
        // Get the nonpublic methods.
        MethodInfo[] myArrayMethodInfo1 =
myType.GetMethods(BindingFlags.NonPublic|BindingFlags.Instance|BindingFla
gs.DeclaredOnly);
        Console.WriteLine("\nThe number of protected methods is {0}.",
myArrayMethodInfo1.Length);
        // Display information for all methods.
        DisplayMethodInfo(myArrayMethodInfo1);
    }
    public static void DisplayMethodInfo(MethodInfo[] myArrayMethodInfo)
    {
        // Display information for all methods.
        for(int i=0;i<myArrayMethodInfo.Length;i++)
        {
            MethodInfo myMethodInfo = (MethodInfo)myArrayMethodInfo[i];
            Console.WriteLine("\nThe name of the method is {0}.",
myMethodInfo.Name);
        }
    }
}
```

Remarks

For the `GetMethods(BindingFlags)` overload to successfully retrieve method information, the `bindingAttr` argument must include at least one of BindingFlags.Instance and BindingFlags.Static, along with at least one of BindingFlags.NonPublic and BindingFlags.Public.

The following BindingFlags filter flags can be used to define which methods to include in the search:

- Specify `BindingFlags.Instance` to include instance methods.
- Specify `BindingFlags.Static` to include static methods.
- Specify `BindingFlags.Public` to include public methods in the search.
- Specify `BindingFlags.NonPublic` to include non-public methods (that is, private, internal, and protected methods) in the search. Only protected and internal

methods on base classes are returned; private methods on base classes are not returned.

- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.
- Specify `BindingFlags.Default` alone to return an empty MethodInfo array.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.DeclaredOnly` to search only the methods declared on the Type, not methods that were simply inherited.

See System.Reflection.BindingFlags for more information.

In .NET 6 and earlier versions, the GetMethods method does not return methods in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which methods are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

If the current Type represents a constructed generic type, this method returns the MethodInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the methods of Object if there is no class constraint.

.NET Standard	2.0, 2.1

GetMethods()

Returns all the public methods of the current Type.

```
C#
public System.Reflection.MethodInfo[] GetMethods ();
```

Returns

MethodInfo[]

An array of MethodInfo objects representing all the public methods defined for the current Type.

-or-

An empty array of type MethodInfo, if no public methods are defined for the current Type.

Remarks

In .NET 6 and earlier versions, the GetMethods method does not return methods in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which methods are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

Constructors are not included in the array of methods returned by this call. Make a separate call to `GetConstructors()` to get the constructor methods.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

> **Note**
>
> You cannot omit parameters when looking up constructors and methods. You can only omit parameters when invoking.

If the current Type represents a constructed generic type, this method returns the MethodInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the methods of the class constraint, or the

methods of Object if there is no class constraint.

Type.GetNestedType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific type nested within the current Type.

Overloads

Expand table

GetNestedType(String)	Searches for the public nested type with the specified name.
GetNestedType(String, BindingFlags)	When overridden in a derived class, searches for the specified nested type, using the specified binding constraints.

GetNestedType(String)

Searches for the public nested type with the specified name.

C#

```
public Type? GetNestedType (string name);
```

Parameters

name String

The string containing the name of the nested type to get.

Returns

Type

An object representing the public nested type with the specified name, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

Remarks

The search for `name` is case-sensitive.

Use the simple name of the nested class for `name`. Do not qualify it with the name of the outer class. For a generic nested class, use the mangled name - that is, append a grave accent and the number of generic arguments. For example, use the string "Inner`1" to get the generic nested class `Inner<T>` (`Inner(Of T)` in Visual Basic). Do not include language-specific syntax for type parameters.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the nested types of the class constraint.

If a nested type is generic, this method returns its generic type definition. This is true even if the enclosing generic type is a closed constructed type.

> ⓘ **Note**
>
> If the current **Type** represents a generic type defined in C#, Visual Basic, or C++, its nested types are all generic even if they have no generic parameters of their own. This is not necessarily true of nested types defined in dynamic assemblies or compiled with the **Ilasm.exe (IL Assembler)**.

For information on nested generic types, and on constructing nested generic types from their generic type definitions, see MakeGenericType.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetNestedType(String, BindingFlags)

When overridden in a derived class, searches for the specified nested type, using the specified binding constraints.

```
C#

public abstract Type? GetNestedType (string name,
System.Reflection.BindingFlags bindingAttr);
```

Parameters

`name` String

The string containing the name of the nested type to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

Returns

Type

An object representing the nested type that matches the specified requirements, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`name` is `null`.

Remarks

Use the simple name of the nested class for `name`. Do not qualify it with the name of the outer class. For a generic nested class, use the mangled name - that is, append a grave accent and the number of generic parameters. For example, use the string "Inner`1" to get the generic nested class `Inner<T>` (`Inner(Of T)` in Visual Basic). Do not include language-specific syntax for type parameters.

The following BindingFlags filter flags can be used to define which nested types to include in the search:

- You must specify either BindingFlags.Public or BindingFlags.NonPublic to get a return.
- Specify BindingFlags.Public to include public nested types in the search.
- Specify BindingFlags.NonPublic to include non-public nested types (that is, private, internal, and protected nested types) in the search.

This method returns only the nested types of the current type. It does not search the base classes of the current type. To find types that are nested in base classes, you must walk the inheritance hierarchy, calling GetNestedType at each level.

BindingFlags.Instance and BindingFlags.Static are ignored.

Calling this method with only the BindingFlags.Public flag or only the BindingFlags.NonPublic flag will return the specified nested types and does not require any other flags.

See System.Reflection.BindingFlags for more information.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the nested types of the class constraint.

If a nested type is generic, this method returns its generic type definition. This is true even if the enclosing generic type is a closed constructed type.

> **Note**
>
> If the current **Type** represents a generic type defined in C#, Visual Basic, or C++, its nested types are all generic even if they have no generic parameters of their own. This is not necessarily true of nested types defined in dynamic assemblies or compiled with the **Ilasm.exe (IL Assembler)**.

For information on nested generic types, and on constructing nested generic types from their generic type definitions, see MakeGenericType.

Type.GetNestedTypes Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the types nested within the current Type.

Overloads

Expand table

GetNestedTypes()	Returns the public types nested in the current Type.
GetNestedTypes(BindingFlags)	When overridden in a derived class, searches for the types nested in the current Type, using the specified binding constraints.

GetNestedTypes()

Returns the public types nested in the current Type.

C#

```
public Type[] GetNestedTypes ();
```

Returns

Type[]

An array of Type objects representing the public types nested in the current Type (the search is not recursive), or an empty array of type Type if no public types are nested in the current Type.

Examples

The following example defines a nested class and a `struct` in `MyClass`, and then obtains objects of the nested types using the type of `MyClass`.

C#

```
using System;
using System.Reflection;
public class MyClass
{
    public class NestClass
    {
        public static int myPublicInt=0;
    }
    public struct NestStruct
    {
        public static int myPublicInt=0;
    }
}

public class MyMainClass
{
    public static void Main()
    {
        try
        {
            // Get the Type object corresponding to MyClass.
            Type myType=typeof(MyClass);
            // Get an array of nested type objects in MyClass.
            Type[] nestType=myType.GetNestedTypes();
            Console.WriteLine("The number of nested types is {0}.",
nestType.Length);
            foreach(Type t in nestType)
                Console.WriteLine("Nested type is {0}.", t.ToString());
        }
        catch(Exception e)
        {
            Console.WriteLine("Error"+e.Message);
        }
    }
}
```

Remarks

In .NET 6 and earlier versions, the GetNestedTypes method does not return types in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which types are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

Only the public types immediately nested in the current type are returned; the search is not recursive.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the nested types of the class constraint.

If a nested type is generic, this method returns its generic type definition. This is true even if the enclosing generic type is a closed constructed type.

> **Note**
>
> If the current **Type** represents a generic type defined in C#, Visual Basic, or C++, its nested types are all generic even if they have no generic parameters of their own. This is not necessarily true of nested types defined in dynamic assemblies or compiled with the **Ilasm.exe (IL Assembler)**.

For information on nested generic types, and on constructing nested generic types from their generic type definitions, see MakeGenericType.

- GetNestedType(String)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetNestedTypes(BindingFlags)

When overridden in a derived class, searches for the types nested in the current Type, using the specified binding constraints.

C#

```
public abstract Type[] GetNestedTypes (System.Reflection.BindingFlags
bindingAttr);
```

Parameters

bindingAttr	BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

Returns

Type[]

An array of Type objects representing all the types nested in the current Type that match the specified binding constraints (the search is not recursive), or an empty array of type Type, if no nested types are found that match the binding constraints.

Examples

The following example creates two nested public classes and two nested protected classes, and displays information for classes that match the specified binding constraints.

C#

```
using System;
using System.Reflection;

// Create a class with 2 nested public and 2 nested protected classes.
public class MyTypeClass
{
    public class Myclass1
    {
    }

    public class Myclass2
    {
    }

    protected class MyClass3
    {
    }

    protected class MyClass4
    {
    }
}

public class TypeMain
{
    public static void Main()
```

```
    {
        Type myType = (typeof(MyTypeClass));
        // Get the public nested classes.
        Type[] myTypeArray = myType.GetNestedTypes(BindingFlags.Public);
        Console.WriteLine("The number of nested public classes is {0}.",
myTypeArray.Length);
        // Display all the public nested classes.
        DisplayTypeInfo(myTypeArray);
        Console.WriteLine();

        // Get the nonpublic nested classes.
        Type[] myTypeArray1 =
myType.GetNestedTypes(BindingFlags.NonPublic|BindingFlags.Instance);
        Console.WriteLine("The number of nested protected classes is
{0}.", myTypeArray1.Length);
        // Display all the nonpublic nested classes.
        DisplayTypeInfo(myTypeArray1);
    }

    public static void DisplayTypeInfo(Type[] myArrayType)
    {
        // Display the information for all the nested classes.
        foreach (var t in myArrayType)
            Console.WriteLine("The name of the nested class is {0}.",
t.FullName);
    }
}
// The example displays the following output:
//       The number of public nested classes is 2.
//       The name of the nested class is MyTypeClass+Myclass1.
//       The name of the nested class is MyTypeClass+Myclass2.
//
//       The number of protected nested classes is 2.
//       The name of the nested class is MyTypeClass+MyClass3.
//       The name of the nested class is MyTypeClass+MyClass4.
```

Remarks

The search for nested types is not recursive.

In .NET 6 and earlier versions, the GetNestedTypes method does not return types in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which types are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following BindingFlags filter flags can be used to define which nested types to include in the search:

- You must specify either BindingFlags.Public or BindingFlags.NonPublic to get a return.
- Specify BindingFlags.Public to include public nested types in the search.
- Specify BindingFlags.NonPublic to include non-public nested types (that is, private, internal, and protected nested types) in the search.

This method returns only the nested types of the current type. It does not search the base classes of the current type. To find types that are nested in base classes, you must walk the inheritance hierarchy, calling GetNestedTypes at each level.

BindingFlags.Instance and BindingFlags.Static are ignored.

Calling this method with only the BindingFlags.Public flag or only the BindingFlags.NonPublic flag will return the specified nested types and does not require any other flags.

See System.Reflection.BindingFlags for more information.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the nested types of the class constraint.

If a nested type is generic, this method returns its generic type definition. This is true even if the enclosing generic type is a closed constructed type.

> **Note**
>
> If the current **Type** represents a generic type defined in C#, Visual Basic, or C++, its nested types are all generic even if they have no generic parameters of their own. This is not necessarily true of nested types defined in dynamic assemblies or compiled with the **Ilasm.exe (IL Assembler)**.

For information on nested generic types, and on constructing nested generic types from their generic type definitions, see MakeGenericType.

Type.GetOptionalCustomModifiers Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the optional custom modifiers of the current Type.

```
C#

public virtual Type[] GetOptionalCustomModifiers ();
```

Returns

Type[]

An array of Type objects that identify the optional custom modifiers of the current Type.

-or-

An empty array of type Type, if the current Type has no custom modifiers.

-or-

An empty array of type Type, if the current Type is not a modified Type. A modified Type is obtained from GetModifiedFieldType(), GetModifiedPropertyType(), or GetModifiedParameterType().

Remarks

The GetOptionalCustomModifiers and GetRequiredCustomModifiers methods are provided for designers of managed compilers. For more information on custom modifiers, see classes in the System.Runtime.CompilerServices namespace. Also see the metadata specification in Partition II of the Common Language Infrastructure (CLI) documentation.

Applies to

Type.GetProperties Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the properties of the current Type.

Overloads

Expand table

GetProperties()	Returns all the public properties of the current Type.
GetProperties(BindingFlags)	When overridden in a derived class, searches for the properties of the current Type, using the specified binding constraints.

GetProperties()

Returns all the public properties of the current Type.

C#

```
public System.Reflection.PropertyInfo[] GetProperties ();
```

Returns

PropertyInfo[]

An array of PropertyInfo objects representing all public properties of the current Type.

-or-

An empty array of type PropertyInfo, if the current Type does not have public properties.

Examples

The following example demonstrates the use of the `GetProperties` method.

C#

```
PropertyInfo[] myPropertyInfo;
// Get the properties of 'Type' class object.
myPropertyInfo = Type.GetType("System.Type").GetProperties();
Console.WriteLine("Properties of System.Type are:");
for (int i = 0; i < myPropertyInfo.Length; i++)
{
    Console.WriteLine(myPropertyInfo[i].ToString());
}
```

Remarks

Calling this overload is equivalent to calling the GetProperties(BindingFlags) overload with a `bindingAttr` argument equal to `BindingFlags.Instance | BindingFlags.Static | BindingFlags.Public` in C# and `BindingFlags.Instance Or BindingFlags.Static Or BindingFlags.Public` in Visual Basic. It returns all public instance and static properties, both those defined by the type represented by the current Type object as well as those inherited from its base types.

A property is considered public to reflection if it has at least one accessor that is public. Otherwise the property is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

In .NET 6 and earlier versions, the GetProperties method does not return properties in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which properties are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No

Member Type	Static	Non-Static
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

If the current Type represents a constructed generic type, this method returns the PropertyInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the properties of the class constraint.

.NET Standard	2.0, 2.1

GetProperties(BindingFlags)

When overridden in a derived class, searches for the properties of the current Type, using the specified binding constraints.

C#

```
public abstract System.Reflection.PropertyInfo[] GetProperties
(System.Reflection.BindingFlags bindingAttr);
```

Parameters

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return an empty array.

Returns

PropertyInfo[]

An array of objects representing all properties of the current Type that match the specified binding constraints.

-or-

An empty array of type PropertyInfo, if the current Type does not have properties, or if none of the properties match the binding constraints.

Implements

GetProperties(BindingFlags)

Examples

The following example defines a class named `PropertyClass` that includes six properties: two are public, one is private, one is protected, one is internal (`Friend` in Visual Basic), and one is protected internal (`Protected Friend` in Visual Basic). It then displays some basic property information (the property name and type, whether it is read/write, and the visibility of its `get` and `set` accessors) for the properties that match the specified binding constraints.

C#

```
using System;
using System.Reflection;

// Create a class having six properties.
public class PropertyClass
{
    public String Property1
    {
        get { return "hello"; }
    }

    public String Property2
    {
        get { return "hello"; }
    }

    protected String Property3
    {
        get { return "hello"; }
    }

    private Int32 Property4
    {
        get { return 32; }
    }

    internal String Property5
    {
       get { return "value"; }
    }

    protected internal String Property6
    {
       get { return "value"; }
    }
}

public class Example
{
    public static void Main()
```

```
    {
        Type t = typeof(PropertyClass);
        // Get the public properties.
        PropertyInfo[] propInfos =
t.GetProperties(BindingFlags.Public|BindingFlags.Instance);
        Console.WriteLine("The number of public properties: {0}.\n",
                          propInfos.Length);
        // Display the public properties.
        DisplayPropertyInfo(propInfos);

        // Get the nonpublic properties.
        PropertyInfo[] propInfos1 =
t.GetProperties(BindingFlags.NonPublic|BindingFlags.Instance);
        Console.WriteLine("The number of non-public properties: {0}.\n",
                          propInfos1.Length);
        // Display all the nonpublic properties.
        DisplayPropertyInfo(propInfos1);
    }

    public static void DisplayPropertyInfo(PropertyInfo[] propInfos)
    {
        // Display information for all properties.
        foreach (var propInfo in propInfos) {
            bool readable = propInfo.CanRead;
            bool writable = propInfo.CanWrite;

            Console.WriteLine("   Property name: {0}", propInfo.Name);
            Console.WriteLine("   Property type: {0}",
propInfo.PropertyType);
            Console.WriteLine("   Read-Write:    {0}", readable &
writable);
            if (readable) {
               MethodInfo getAccessor = propInfo.GetMethod;
               Console.WriteLine("   Visibility:    {0}",
                                 GetVisibility(getAccessor));
            }
            if (writable) {
               MethodInfo setAccessor = propInfo.SetMethod;
               Console.WriteLine("   Visibility:    {0}",
                                 GetVisibility(setAccessor));
            }
            Console.WriteLine();
        }
    }

    public static String GetVisibility(MethodInfo accessor)
    {
       if (accessor.IsPublic)
          return "Public";
       else if (accessor.IsPrivate)
          return "Private";
       else if (accessor.IsFamily)
          return "Protected";
       else if (accessor.IsAssembly)
          return "Internal/Friend";
```

```
        else
           return "Protected Internal/Friend";
    }
}
// The example displays the following output:
//       The number of public properties: 2.
//
//          Property name: Property1
//          Property type: System.String
//          Read-Write:    False
//          Visibility:    Public
//
//          Property name: Property2
//          Property type: System.String
//          Read-Write:    False
//          Visibility:    Public
//
//       The number of non-public properties: 4.
//
//          Property name: Property3
//          Property type: System.String
//          Read-Write:    False
//          Visibility:    Protected
//
//          Property name: Property4
//          Property type: System.Int32
//          Read-Write:    False
//          Visibility:    Private
//
//          Property name: Property5
//          Property type: System.String
//          Read-Write:    False
//          Visibility:    Internal/Friend
//
//          Property name: Property6
//          Property type: System.String
//          Read-Write:    False
//          Visibility:    Protected Internal/Friend
```

Remarks

For the `GetProperties(BindingFlags)` overload to successfully retrieve property information, the `bindingAttr` argument must include at least one of BindingFlags.Instance and BindingFlags.Static, along with at least one of BindingFlags.NonPublic and BindingFlags.Public.

The following BindingFlags filter flags can be used to define which properties to include in the search:

- Specify `BindingFlags.Instance` to include instance methods.

- Specify `BindingFlags.Static` to include static methods.
- Specify `BindingFlags.Public` to include public properties in the search. A property is considered public to reflection if it has at least one accessor that is public.
- Specify `BindingFlags.NonPublic` to include non-public properties (that is, private, internal, and protected properties) in the search. Only protected and internal properties on base classes are returned; private properties on base classes are not returned.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.
- Specify `BindingFlags.Default` alone to return an empty PropertyInfo array.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.DeclaredOnly` to search only the properties declared on the Type, not properties that were simply inherited.

See System.Reflection.BindingFlags for more information.

In .NET 6 and earlier versions, the GetProperties method does not return properties in a particular order, such as alphabetical or declaration order. Your code must not depend on the order in which properties are returned, because that order varies. However, starting with .NET 7, the ordering is deterministic based upon the metadata ordering in the assembly.

If the current Type represents a constructed generic type, this method returns the PropertyInfo objects with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the properties of the class constraint.

Type.GetProperty Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a specific property of the current Type.

Overloads

Expand table

GetProperty(String, BindingFlags, Binder, Type, Type[], ParameterModifier[])	Searches for the specified property whose parameters match the specified argument types and modifiers, using the specified binding constraints.
GetProperty(String, Type, Type[], ParameterModifier[])	Searches for the specified public property whose parameters match the specified argument types and modifiers.
GetProperty(String, Type[])	Searches for the specified public property whose parameters match the specified argument types.
GetProperty(String, Type, Type[])	Searches for the specified public property whose parameters match the specified argument types.
GetProperty(String, BindingFlags)	Searches for the specified property, using the specified binding constraints.
GetProperty(String)	Searches for the public property with the specified name.
GetProperty(String, Type)	Searches for the public property with the specified name and return type.

GetProperty(String, BindingFlags, Binder, Type, Type[], ParameterModifier[])

Searches for the specified property whose parameters match the specified argument types and modifiers, using the specified binding constraints.

```
C#

public System.Reflection.PropertyInfo? GetProperty (string name,
System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, Type? returnType, Type[] types,
System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`name` String

The string containing the name of the property to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`returnType` Type

The return type of the property.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the indexed property to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a property that is not indexed.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

PropertyInfo

An object representing the property that matches the specified requirements, if found; otherwise, `null`.

Implements

GetProperty(String, BindingFlags, Binder, Type, Type[], ParameterModifier[])

Exceptions

AmbiguousMatchException

More than one property is found with the specified name and matching the specified binding constraints.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

NullReferenceException

An element of `types` is `null`.

Remarks

For more information about this API, see Supplemental API remarks for Type.GetProperty.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetProperty(String, Type, Type[], ParameterModifier[])

Searches for the specified public property whose parameters match the specified argument types and modifiers.

C#

```
public System.Reflection.PropertyInfo? GetProperty (string name, Type?
returnType, Type[] types, System.Reflection.ParameterModifier[]?
modifiers);
```

Parameters

name String

The string containing the name of the public property to get.

`returnType` Type

The return type of the property.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the indexed property to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a property that is not indexed.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

PropertyInfo

An object representing the public property that matches the specified requirements, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one property is found with the specified name and matching the specified argument types and modifiers.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

NullReferenceException

An element of `types` is `null`.

Examples

The following example obtains a `Type` object corresponding to `MyPropertyClass`, and the indexed property of this class is retrieved using the arguments passed to the `GetProperty` method.

C#

```
using System;
using System.Reflection;

public class MyPropertyClass
{
    private int [,] myPropertyArray = new int[10,10];
    // Declare an indexer.
    public int this [int i,int j]
    {
        get
        {
            return myPropertyArray[i,j];
        }
        set
        {
            myPropertyArray[i,j] = value;
        }
    }
}

public class MyTypeClass
{
    public static void Main()
    {
        try
        {
            Type myType=typeof(MyPropertyClass);
            Type[] myTypeArray = new Type[2];
            // Create an instance of the Type array representing the
number, order
            // and type of the parameters for the property.
            myTypeArray.SetValue(typeof(int),0);
            myTypeArray.SetValue(typeof(int),1);
```

```
            // Search for the indexed property whose parameters match the
            // specified argument types and modifiers.
            PropertyInfo myPropertyInfo = myType.GetProperty("Item",
                typeof(int),myTypeArray,null);
            Console.WriteLine(myType.FullName + "." + myPropertyInfo.Name
+
                " has a property type of " +
myPropertyInfo.PropertyType);
         }
        catch(Exception ex)
        {
            Console.WriteLine("An exception occurred " + ex.Message);
        }
    }
}
```

Remarks

A property is considered public to reflection if it has at least one accessor that is public. Otherwise the property is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

The search for `name` is case-sensitive. The search includes public static and public instance properties.

If the current Type represents a constructed generic type, this method returns the PropertyInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the properties of the class constraint.

.NET Standard	2.0, 2.1

GetProperty(String, Type[])

Searches for the specified public property whose parameters match the specified argument types.

C#

```
public System.Reflection.PropertyInfo? GetProperty (string name, Type[] types);
```

Parameters

`name` String

The string containing the name of the public property to get.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the indexed property to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a property that is not indexed.

Returns

PropertyInfo

An object representing the public property whose parameters match the specified argument types, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one property is found with the specified name and matching the specified argument types.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

ArgumentException

`types` is multidimensional.

NullReferenceException

An element of `types` is `null`.

Examples

The following example retrieves the `Type` object of a user-defined class, retrieves the property of that class, and displays the property name and type of the property as specified by the arguments passed to `GetProperty`.

C#

```
using System;
using System.Reflection;

class MyClass3
{
    private int [,] myArray = {{1,2},{3,4}};
    // Declare an indexer.
    public int this [int i,int j]
    {
        get
        {
            return myArray[i,j];
        }
        set
```

```
        {
            myArray[i,j] = value;
        }
    }
}

public class MyTypeClass3
{
    public static void Main(string[] args)
    {
        try
        {
            // Get the Type object.
            Type myType=typeof(MyClass3);
            Type[] myTypeArr = new Type[2];
            // Create an instance of a Type array.
            myTypeArr.SetValue(typeof(int),0);
            myTypeArr.SetValue(typeof(int),1);
            // Get the PropertyInfo object for the indexed property Item,
which has two integer parameters.
            PropertyInfo myPropInfo = myType.GetProperty("Item",
myTypeArr);
            // Display the property.
            Console.WriteLine("The {0} property exists in MyClass3.",
myPropInfo.ToString());
        }
        catch(NullReferenceException e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Source : {0}" , e.Source);
            Console.WriteLine("Message : {0}" , e.Message);
        }
    }
}
```

Remarks

A property is considered public to reflection if it has at least one accessor that is public. Otherwise the property is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

GetProperty(String, BindingFlags)

Searches for the specified property, using the specified binding constraints.

C#

```
public System.Reflection.PropertyInfo? GetProperty (string name,
System.Reflection.BindingFlags bindingAttr);
```

Parameters

`name` String

The string containing the name of the property to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

Returns

PropertyInfo

An object representing the property that matches the specified requirements, if found; otherwise, `null`.

Implements

GetProperty(String, BindingFlags)

Exceptions

AmbiguousMatchException

More than one property is found with the specified name and matching the specified binding constraints.

ArgumentNullException

`name` is `null`.

Examples

The following example retrieves the type of a user-defined class, retrieves a property of that class and displays the property name in accordance with the specified binding constraints.

C#

```
using System;
using System.Reflection;

class MyClass2
{
```

```
    private int myProperty;
    // Declare MyProperty.
    public int MyProperty
    {
        get
        {
            return myProperty;
        }
        set
        {
            myProperty=value;
        }
    }
}

public class MyTypeClass2
{
    public static void Main(string[] args)
    {
        try
        {
            // Get Type object of MyClass2.
            Type myType=typeof(MyClass2);
            // Get the PropertyInfo by passing the property name and
specifying the BindingFlags.
            PropertyInfo myPropInfo = myType.GetProperty("MyProperty",
BindingFlags.Public | BindingFlags.Instance);
            // Display Name property to console.
            Console.WriteLine("{0} is a property of MyClass2.",
myPropInfo.Name);
        }
        catch(NullReferenceException e)
        {
            Console.WriteLine("MyProperty does not exist in MyClass2."
+e.Message);
        }
    }
}
```

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetProperty(String)

Searches for the public property with the specified name.

```
C#

public System.Reflection.PropertyInfo? GetProperty (string name);
```

Parameters

`name` String

The string containing the name of the public property to get.

Returns

PropertyInfo

An object representing the public property with the specified name, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one property is found with the specified name.

ArgumentNullException

`name` is `null`.

Examples

The following example retrieves the `Type` object of a user-defined class, retrieves a property of that class, and displays the property name.

C#

```
using System;
using System.Reflection;

class MyClass1
{
    private int myProperty;
    // Declare MyProperty.
    public int MyProperty
    {
        get
        {
            return myProperty;
        }
        set
        {
            myProperty=value;
        }
    }
}

public class MyTypeClass2
{
    public static void Main(string[] args)
    {
        try
        {
            // Get the Type object corresponding to MyClass1.
            Type myType=typeof(MyClass1);
            // Get the PropertyInfo object by passing the property name.
            PropertyInfo myPropInfo = myType.GetProperty("MyProperty");
            // Display the property name.
            Console.WriteLine("The {0} property exists in MyClass1.",
myPropInfo.Name);
        }
        catch(NullReferenceException e)
        {
            Console.WriteLine("The property does not exist in MyClass1."
+ e.Message);
        }
    }
}
```

Remarks

For more information about this API, see Supplemental API remarks for Type.GetProperty.

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetProperty(String, Type)

Searches for the public property with the specified name and return type.

C#

```
public System.Reflection.PropertyInfo? GetProperty (string name, Type?
returnType);
```

Parameters

`name` String

The string containing the name of the public property to get.

`returnType` Type

The return type of the property.

Returns

PropertyInfo

An object representing the public property with the specified name, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one property is found with the specified name.

ArgumentNullException

`name` is `null`, or `returnType` is `null`.

Examples

The following example defines a class with one property and retrieves the name and type of the property.

C#

```
using System;
using System.Reflection;

class MyPropertyTypeClass
{
    String myMessage = "Hello World.";
    public string MyProperty1
    {
        get
        {
            return myMessage;
        }
        set
        {
            myMessage = value;
        }
    }
}

class TestClass
{
    static void Main()
    {
        try
        {
            Type myType = typeof(MyPropertyTypeClass);
```

```
            // Get the PropertyInfo object representing MyProperty1.
            PropertyInfo myStringProperties1 =
myType.GetProperty("MyProperty1", typeof(string));
            Console.WriteLine("The name of the first property of
MyPropertyTypeClass is {0}.", myStringProperties1.Name);
            Console.WriteLine("The type of the first property of
MyPropertyTypeClass is {0}.", myStringProperties1.PropertyType);
        }
        catch(ArgumentNullException e)
        {
            Console.WriteLine("ArgumentNullException :" + e.Message);
        }
        catch(AmbiguousMatchException e)
        {
            Console.WriteLine("AmbiguousMatchException :" + e.Message);
        }
        catch(NullReferenceException e)
        {
            Console.WriteLine("Source : {0}" , e.Source);
            Console.WriteLine("Message : {0}" , e.Message);
        }
    //Output:
    //The name of the first property of MyPropertyTypeClass is
MyProperty1.
    //The type of the first property of MyPropertyTypeClass is
System.String.
    }
}
```

Remarks

A property is considered public to reflection if it has at least one accessor that is public. Otherwise the property is considered private, and you must use BindingFlags.NonPublic | BindingFlags.Instance | BindingFlags.Static (in Visual Basic, combine the values using `Or`) to get it.

The search for `name` is case-sensitive. The search includes public static and public instance properties.

If the current Type represents a constructed generic type, this method returns the PropertyInfo with the type parameters replaced by the appropriate type arguments.

If the current Type represents a type parameter in the definition of a generic type or generic method, this method searches the properties of the class constraint.

Type.GetPropertyImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, searches for the specified property whose parameters match the specified argument types and modifiers, using the specified binding constraints.

C#

```
protected abstract System.Reflection.PropertyInfo? GetPropertyImpl (string
name, System.Reflection.BindingFlags bindingAttr, System.Reflection.Binder?
binder, Type? returnType, Type[]? types,
System.Reflection.ParameterModifier[]? modifiers);
```

Parameters

`name` String

The string containing the name of the property to get.

`bindingAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted.

-or-

Default to return `null`.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded member, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder.

`returnType` Type

The return type of the property.

`types` Type[]

An array of Type objects representing the number, order, and type of the parameters for the indexed property to get.

-or-

An empty array of the type Type (that is, Type[] types = new Type[0]) to get a property that is not indexed.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `types` array. The default binder does not process this parameter.

Returns

PropertyInfo

An object representing the property that matches the specified requirements, if found; otherwise, `null`.

Exceptions

AmbiguousMatchException

More than one property is found with the specified name and matching the specified binding constraints.

ArgumentNullException

`name` is `null`.

-or-

`types` is `null`.

-or-

One of the elements in `types` is `null`.

ArgumentException

`types` is multidimensional.

-or-

`modifiers` is multidimensional.

-or-

`types` and `modifiers` do not have the same length.

NotSupportedException
The current type is a TypeBuilder, EnumBuilder, or GenericTypeParameterBuilder.

Remarks

Although the default binder does not process ParameterModifier (the `modifiers` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

The following BindingFlags filter flags can be used to define which properties to include in the search:

- You must specify either `BindingFlags.Instance` or `BindingFlags.Static` in order to get a return.
- Specify `BindingFlags.Public` to include public properties in the search.
- Specify `BindingFlags.NonPublic` to include non-public properties (that is, private, internal, and protected properties) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include `public` and `protected` static members up the hierarchy; `private` static members in inherited classes are not included.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the properties declared on the Type, not properties that were simply inherited.

See System.Reflection.BindingFlags for more information.

Type.GetRequiredCustomModifiers Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, returns the required custom modifiers of the current Type.

C#

```
public virtual Type[] GetRequiredCustomModifiers ();
```

Returns

Type[]

An array of Type objects that identify the required custom modifiers of the current Type.

-or-

An empty array of type Type, if the current Type has no custom modifiers.

-or-

An empty array of type Type, if the current Type is not a modified Type. A modified Type is obtained from GetModifiedFieldType(), GetModifiedPropertyType(), or GetModifiedParameterType().

Remarks

The GetRequiredCustomModifiers and GetRequiredCustomModifiers methods are provided for designers of managed compilers. For more information on custom modifiers, see classes in the System.Runtime.CompilerServices namespace. Also see the metadata specification in Partition II of the Common Language Infrastructure (CLI) documentation.

Type.GetType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a Type object that represents the specified type.

Overloads

Expand table

GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean)	Gets the type with the specified name, specifying whether to perform a case-sensitive search and whether to throw an exception if the type is not found, and optionally providing custom methods to resolve the assembly and the type.
GetType()	Gets the current Type.
GetType(String)	Gets the Type with the specified name, performing a case-sensitive search.
GetType(String, Boolean)	Gets the Type with the specified name, performing a case-sensitive search and specifying whether to throw an exception if the type is not found.
GetType(String, Boolean, Boolean)	Gets the Type with the specified name, specifying whether to throw an exception if the type is not found and whether to perform a case-sensitive search.
GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>)	Gets the type with the specified name, optionally providing custom methods to resolve the assembly and the type.
GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean)	Gets the type with the specified name, specifying whether to throw an exception if the type is not found, and optionally providing custom methods to resolve the assembly and the type.

GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean)

Gets the type with the specified name, specifying whether to perform a case-sensitive search and whether to throw an exception if the type is not found, and optionally providing custom methods to resolve the assembly and the type.

C#

```
public static Type? GetType (string typeName,
Func<System.Reflection.AssemblyName,System.Reflection.Assembly?>?
assemblyResolver, Func<System.Reflection.Assembly?,string,bool,Type?>?
typeResolver, bool throwOnError, bool ignoreCase);
```

Parameters

`typeName` String

The name of the type to get. If the `typeResolver` parameter is provided, the type name can be any string that `typeResolver` is capable of resolving. If the `assemblyResolver` parameter is provided or if standard type resolution is used, `typeName` must be an assembly-qualified name (see AssemblyQualifiedName), unless the type is in the currently executing assembly or in mscorlib.dll/System.Private.CoreLib.dll, in which case it is sufficient to supply the type name qualified by its namespace.

`assemblyResolver` Func<AssemblyName,Assembly>

A method that locates and returns the assembly that is specified in `typeName`. The assembly name is passed to `assemblyResolver` as an AssemblyName object. If `typeName` does not contain the name of an assembly, `assemblyResolver` is not called. If `assemblyResolver` is not supplied, standard assembly resolution is performed.

Caution Do not pass methods from unknown or untrusted callers. Doing so could result in elevation of privilege for malicious code. Use only methods that you provide or that you are familiar with.

`typeResolver` Func<Assembly,String,Boolean,Type>

A method that locates and returns the type that is specified by `typeName` from the assembly that is returned by `assemblyResolver` or by standard assembly resolution. If no assembly is provided, the method can provide one. The method also takes a parameter that specifies whether to perform a case-insensitive search; the value of `ignoreCase` is passed to that parameter.

Caution Do not pass methods from unknown or untrusted callers.

`throwOnError` Boolean

`true` to throw an exception if the type cannot be found; `false` to return `null`. Specifying `false` also suppresses some other exception conditions, but not all of them. See the Exceptions section.

`ignoreCase` Boolean

`true` to perform a case-insensitive search for `typeName`, `false` to perform a case-sensitive search for `typeName`.

Returns

Type

The type with the specified name. If the type is not found, the `throwOnError` parameter specifies whether `null` is returned or an exception is thrown. In some cases, an exception is thrown regardless of the value of `throwOnError`. See the Exceptions section.

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

TypeLoadException

`throwOnError` is `true` and the type is not found.

-or-

`throwOnError` is `true` and `typeName` contains invalid characters, such as an embedded tab.

-or-

`throwOnError` is `true` and `typeName` is an empty string.

-or-

`throwOnError` is `true` and `typeName` represents an array type with an invalid size.

-or-

`typeName` represents an array of TypedReference.

ArgumentException

An error occurs when `typeName` is parsed into a type name and an assembly name (for example, when the simple type name includes an unescaped special character).

-or-

`throwOnError` is `true` and `typeName` contains invalid syntax (for example, "MyType[,*,]").

-or-

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

FileNotFoundException

`throwOnError` is `true` and the assembly or one of its dependencies was not found.

FileLoadException

The assembly or one of its dependencies was found, but could not be loaded.

-or-

`typeName` contains an invalid assembly name.

-or-

`typeName` is a valid assembly name without a type name.

BadImageFormatException
The assembly or one of its dependencies is not valid.

-or-

The assembly was compiled with a later version of the common language runtime than the version that is currently loaded.

Remarks

For more information about this API, see Supplemental API remarks for Type.GetType.

Applies to

- TypeLoadException
- Specifying Fully Qualified Type Names

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetType(String)

Gets the Type with the specified name, performing a case-sensitive search.

C#

```
public static Type? GetType (string typeName);
```

Parameters

`typeName` String

The assembly-qualified name of the type to get. See AssemblyQualifiedName. If the type is in the currently executing assembly or in mscorlib.dll/System.Private.CoreLib.dll, it is sufficient to supply the type name qualified by its namespace.

Returns

Type

The type with the specified name, if found; otherwise, `null`.

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

ArgumentException

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

TypeLoadException

`typeName` represents an array of TypedReference.

FileLoadException

The assembly or one of its dependencies was found, but could not be loaded.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, IOException, instead.

BadImageFormatException

The assembly or one of its dependencies is not valid.

-or-

Version 2.0 or later of the common language runtime is currently loaded, and the assembly was compiled with a later version.

Examples

The following example retrieves the type of `System.Int32` and uses that type object to display the FullName property of `System.Int32`.

C#

```
using System;

class Example
{
     public static void Main()
     {
         try {
             // Get the type of a specified class.
             Type myType1 = Type.GetType("System.Int32");
             Console.WriteLine("The full name is {0}.\n",
myType1.FullName);
         }
         catch (TypeLoadException e)
         {
            Console.WriteLine("{0}: Unable to load type System.Int32",
e.GetType().Name);
         }

         try {
             // Since NoneSuch does not exist in this assembly, GetType
throws a TypeLoadException.
             Type myType2 = Type.GetType("NoneSuch", true);
             Console.WriteLine("The full name is {0}.",
myType2.FullName);
         }
         catch(TypeLoadException e) {
            Console.WriteLine("{0}: Unable to load type NoneSuch",
e.GetType().Name);
         }
     }
}
// The example displays the following output:
//       The full name is System.Int32.
//
//       TypeLoadException: Unable to load type NoneSuch
```

Remarks

You can use the GetType method to obtain a Type object for a type in another assembly if you know its assembly-qualified name, which can be obtained from AssemblyQualifiedName. GetType causes loading of the assembly specified in `typeName`. You can also load an assembly using the Assembly.Load method, and then use the Assembly.GetType or Assembly.GetTypes method to get Type objects. If a type is in an assembly known to your program at compile time, it is more efficient to use `typeof` in C# or the `GetType` operator in Visual Basic.

ⓘ **Note**

If `typeName` cannot be found, the call to the **GetType(String)** method returns `null`. It does not throw an exception. To control whether an exception is thrown, call an overload of the **GetType** method that has a `throwOnError` parameter.

GetType only works on assemblies loaded from disk. If you call GetType to look up a type defined in a dynamic assembly defined using the System.Reflection.Emit services, you might get inconsistent behavior. The behavior depends on whether the dynamic assembly is persistent, that is, created using the `RunAndSave` or `Save` access modes of the System.Reflection.Emit.AssemblyBuilderAccess enumeration. If the dynamic assembly is persistent and has been written to disk before `GetType` is called, the loader finds the saved assembly on disk, loads that assembly, and retrieves the type from that assembly. If the assembly has not been saved to disk when `GetType` is called, the method returns `null`. `GetType` does not understand transient dynamic assemblies; therefore, calling `GetType` to retrieve a type in a transient dynamic assembly returns `null`.

To use `GetType` on a dynamic module, subscribe to the AppDomain.AssemblyResolve event and call `GetType` before saving. Otherwise, you will get two copies of the assembly in memory.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection

Member Type	Static	Non-Static
	Treat properties as hide-by-name-and-signature. See note 2 below.	

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

Arrays or COM types are not searched for unless they have already been loaded into the table of available classes.

`typeName` can be the type name qualified by its namespace or an assembly-qualified name that includes an assembly name specification. See AssemblyQualifiedName.

If `typeName` includes the namespace but not the assembly name, this method searches only the calling object's assembly and mscorlib.dll/System.Private.CoreLib.dll, in that order. If typeName is fully qualified with the partial or complete assembly name, this method searches in the specified assembly. If the assembly has a strong name, a complete assembly name is required.

The AssemblyQualifiedName property returns a fully qualified type name including nested types, the assembly name, and generic type arguments. All compilers that support the common language runtime will emit the simple name of a nested class, and reflection constructs a mangled name when queried, in accordance with the following conventions.

> **Note**
>
> In the .NET Framework version 2.0, processor architecture is added to assembly identity, and can be specified as part of assembly name strings. For example, "ProcessorArchitecture=msil". However, it is not included in the string returned by the **AssemblyQualifiedName** property, for compatibility reasons. You can also load types by creating an **AssemblyName** object and passing it to an appropriate overload of the **Load** method. You can then use the **Assembly.GetType** method to load types from the assembly. See also **AssemblyName.ProcessorArchitecture**.

Expand table

Delimiter	Meaning
Backslash (\)	Escape character.
Backtick (`)	Precedes one or more digits representing the number of type parameters, located at the end of the name of a generic type.
Brackets ([])	Enclose a generic type argument list, for a constructed generic type; within a type argument list, enclose an assembly-qualified type.
Comma (,)	Precedes the Assembly name.
Period (.)	Denotes namespace identifiers.
Plus sign (+)	Precedes a nested class.

For example, the fully qualified name for a class might look like this:

```
TopNamespace.SubNameSpace.ContainingClass+NestedClass,MyAssembly
```

If the namespace were TopNamespace.Sub+Namespace, then the string would have to precede the plus sign (+) with an escape character (\) to prevent it from being interpreted as a nesting separator. Reflection emits this string as follows:

```
TopNamespace.Sub\+Namespace.ContainingClass+NestedClass,MyAssembly
```

A "++" becomes "\+\+", and a "\" becomes "\\".

This qualified name can be persisted and later used to load the Type. To search for and load a Type, use GetType either with the type name only or with the assembly qualified type name. GetType with the type name only will look for the Type in the caller's assembly and then in the System assembly. GetType with the assembly qualified type name will look for the Type in any assembly.

Type names may include trailing characters that denote additional information about the type, such as whether the type is a reference type, a pointer type or an array type. To retrieve the type name without these trailing characters, use `t.GetElementType().ToString()`, where `t` is the type.

Spaces are relevant in all type name components except the assembly name. In the assembly name, spaces before the ',' separator are relevant, but spaces after the ',' separator are ignored.

The name of a generic type ends with a backtick (`) followed by digits representing the number of generic type arguments. The purpose of this name mangling is to allow compilers to support generic types with the same name but with different numbers of type parameters, occurring in the same scope. For example, reflection returns the mangled names `Tuple`1` and `Tuple`2` from the generic methods `Tuple(Of T)` and `Tuple(Of T0, T1)` in Visual Basic, or `Tuple<T>` and `Tuple<T0, T1>` in Visual C#.

For generic types, the type argument list is enclosed in brackets, and the type arguments are separated by commas. For example, a generic Dictionary<TKey,TValue> has two type parameters. A Dictionary<TKey,TValue> of `MyType` with keys of type String might be represented as follows:

```
System.Collections.Generic.Dictionary`2[System.String,MyType]
```

To specify an assembly-qualified type within a type argument list, enclose the assembly-qualified type within brackets. Otherwise, the commas that separate the parts of the assembly-qualified name are interpreted as delimiting additional type arguments. For example, a Dictionary<TKey,TValue> of `MyType` fromMyAssembly.dll, with keys of type String, might be specified as follows:

```
Type.GetType("System.Collections.Generic.Dictionary`2[System.String,
[MyType,MyAssembly]]")
```

> **Note**
>
> An assembly-qualified type can be enclosed in brackets only when it appears within a type parameter list. The rules for searching assemblies for qualified and unqualified types in type parameter lists are the same as the rules for qualified and unqualified nongeneric types.

Nullable types are a special case of generic types. For example, a nullable Int32 is represented by the string "System.Nullable`1[System.Int32]".

> **Note**
>
> In C#, C++, and Visual Basic you can also get nullable types using type operators. For example, the nullable **Boolean** type is returned by `typeof(Nullable<bool>)` in C#, by `Nullable<Boolean>::typeid` in C++, and by `GetType(Nullable(Of Boolean))` in Visual Basic.

The following table shows the syntax you use with `GetType` for various types.

Expand table

To Get	Use
A nullable Int32	`Type.GetType("System.Nullable`1[System.Int32]")`
An unmanaged pointer to `MyType`	`Type.GetType("MyType*")`
An unmanaged pointer to a pointer to `MyType`	`Type.GetType("MyType**")`
A managed pointer or reference to `MyType`	`Type.GetType("MyType&")`. Note that unlike pointers, references are limited to one level.
A parent class and a nested class	`Type.GetType("MyParentClass+MyNestedClass")`
A one-dimensional array with a lower bound of 0	`Type.GetType("MyType[]")`
A one-dimensional array with an unknown	`Type.GetType("MyType[*]")`

To Get	Use
lower bound	
An n-dimensional array	A comma (,) inside the brackets a total of n-1 times. For example, `System.Object[,,]` represents a three-dimensional `Object` array.
An array of one-dimensional arrays	`Type.GetType("MyType[][]")`
A rectangular two-dimensional array with unknown lower bounds	`Type.GetType("MyType[,]")`
A generic type with one type argument	`Type.GetType("MyGenericType`1[MyType]")`
A generic type with two type arguments	`Type.GetType("MyGenericType`2[MyType,AnotherType]")`
A generic type with two assembly-qualified type arguments	`Type.GetType("MyGenericType`2[[MyType,MyAssembly],[AnotherType,AnotherAssembly]]")`
An assembly-qualified generic type with an assembly-qualified type argument	`Type.GetType("MyGenericType`1[[MyType,MyAssembly]],MyGenericTypeAssembly")`

To Get	Use
A generic type whose type argument is a generic type with two type arguments	`Type.GetType("MyGenericType`1[AnotherGenericType`2[MyType,AnotherType]]")`

GetType(String, Boolean)

Gets the Type with the specified name, performing a case-sensitive search and specifying whether to throw an exception if the type is not found.

```
C#
```

```
public static Type? GetType (string typeName, bool throwOnError);
```

Parameters

`typeName` String

The assembly-qualified name of the type to get. See AssemblyQualifiedName. If the type is in the currently executing assembly or in mscorlib.dll/System.Private.CoreLib.dll, it is sufficient to supply the type name qualified by its namespace.

`throwOnError` Boolean

`true` to throw an exception if the type cannot be found; `false` to return `null`. Specifying `false` also suppresses some other exception conditions, but not all of them. See the Exceptions section.

Returns

Type

The type with the specified name. If the type is not found, the `throwOnError` parameter specifies whether `null` is returned or an exception is thrown. In some cases, an exception is thrown regardless of the value of `throwOnError`. See the Exceptions section.

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

TypeLoadException

`throwOnError` is `true` and the type is not found.

-or-

`throwOnError` is `true` and `typeName` contains invalid characters, such as an embedded tab.

-or-

`throwOnError` is `true` and `typeName` is an empty string.

-or-

`throwOnError` is `true` and `typeName` represents an array type with an invalid size.

-or-

`typeName` represents an array of TypedReference.

ArgumentException

`throwOnError` is `true` and `typeName` contains invalid syntax. For example, "MyType[,*,]".

-or-

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

FileNotFoundException

`throwOnError` is `true` and the assembly or one of its dependencies was not found.

FileLoadException

The assembly or one of its dependencies was found, but could not be loaded.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, IOException, instead.

BadImageFormatException

The assembly or one of its dependencies is not valid.

-or-

Version 2.0 or later of the common language runtime is currently loaded, and the assembly was compiled with a later version.

Examples

The following example retrieves the type of `System.Int32` and uses that type object to display the FullName property of `System.Int32`. If a type object refers to an assembly that does not exist, this example throws an exception.

C#

```
using System;

class Example
{
     public static void Main()
     {
         try {
             // Get the type of a specified class.
             Type myType1 = Type.GetType("System.Int32");
             Console.WriteLine("The full name is {0}.\n",
myType1.FullName);
         }
         catch (TypeLoadException e)
         {
            Console.WriteLine("{0}: Unable to load type System.Int32",
e.GetType().Name);
         }

         try {
             // Since NoneSuch does not exist in this assembly, GetType
throws a TypeLoadException.
             Type myType2 = Type.GetType("NoneSuch", true);
             Console.WriteLine("The full name is {0}.",
myType2.FullName);
         }
         catch(TypeLoadException e) {
            Console.WriteLine("{0}: Unable to load type NoneSuch",
e.GetType().Name);
         }
     }
}
// The example displays the following output:
//       The full name is System.Int32.
//
//       TypeLoadException: Unable to load type NoneSuch
```

Remarks

You can use the GetType method to obtain a Type object for a type in another assembly if you know its assembly-qualified name, which can be obtained from AssemblyQualifiedName. GetType causes loading of the assembly specified in

`typeName`. You can also load an assembly using the Assembly.Load method, and then use the Assembly.GetType or Assembly.GetTypes method to get Type objects. If a type is in an assembly known to your program at compile time, it is more efficient to use `typeof` in C# or the `GetType` operator in Visual Basic.

`GetType` only works on assemblies loaded from disk. If you call `GetType` to look up a type defined in a dynamic assembly defined using the System.Reflection.Emit services, you might get inconsistent behavior. The behavior depends on whether the dynamic assembly is persistent, that is, created using the `RunAndSave` or `Save` access modes of the System.Reflection.Emit.AssemblyBuilderAccess enumeration. If the dynamic assembly is persistent and has been written to disk before `GetType` is called, the loader finds the saved assembly on disk, loads that assembly, and retrieves the type from that assembly. If the assembly has not been saved to disk when `GetType` is called, the method returns `null`. `GetType` does not understand transient dynamic assemblies; therefore, calling `GetType` to retrieve a type in a transient dynamic assembly returns `null`.

To use `GetType` on a dynamic module, subscribe to the AppDomain.AssemblyResolve event and call `GetType` before saving. Otherwise, you will get two copies of the assembly in memory.

The `throwOnError` parameter specifies what happens when the type is not found, and also suppresses certain other exception conditions, as described in the Exceptions section. Some exceptions are thrown regardless of the value of `throwOnError`. For example, if the type is found but cannot be loaded, a TypeLoadException is thrown even if `throwOnError` is `false`.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

Member Type	Static	Non-Static
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

Arrays or COM types are not searched for unless they have already been loaded into the table of available classes.

`typeName` can be the type name qualified by its namespace or an assembly-qualified name that includes an assembly name specification. See AssemblyQualifiedName.

If `typeName` includes the namespace but not the assembly name, this method searches only the calling object's assembly and mscorlib.dll/System.Private.CoreLib.dll, in that order. If typeName is fully qualified with the partial or complete assembly name, this method searches in the specified assembly. If the assembly has a strong name, a complete assembly name is required.

The AssemblyQualifiedName property returns a fully qualified type name including nested types, the assembly name, and generic arguments. All compilers that support the common language runtime will emit the simple name of a nested class, and reflection constructs a mangled name when queried, in accordance with the following conventions.

Note

In the .NET Framework version 2.0, processor architecture is added to assembly identity, and can be specified as part of assembly name strings. For example, "ProcessorArchitecture=msil". However, it is not included in the string returned by the **AssemblyQualifiedName** property, for compatibility reasons. You can also load types by creating an **AssemblyName** object and passing it to an appropriate overload of the **Load** method. You can then use the **Assembly.GetType** method to load types from the assembly. See also **AssemblyName.ProcessorArchitecture**.

Expand table

Delimiter	Meaning
Backslash (\)	Escape character.
Backtick (`)	Precedes one or more digits representing the number of type parameters, located at the end of the name of a generic type.
Brackets ([])	Enclose a generic type argument list, for a constructed generic type; within a type argument list, enclose an assembly-qualified type.
Comma (,)	Precedes the Assembly name.
Period (.)	Denotes namespace identifiers.
Plus sign (+)	Precedes a nested class.

For example, the fully qualified name for a class might look like this:

```
TopNamespace.SubNameSpace.ContainingClass+NestedClass,MyAssembly
```

If the namespace were TopNamespace.Sub+Namespace, then the string would have to precede the plus sign (+) with an escape character (\) to prevent it from being interpreted as a nesting separator. Reflection emits this string as follows:

```
TopNamespace.Sub\+Namespace.ContainingClass+NestedClass,MyAssembly
```

A "++" becomes "\+\+", and a "\" becomes "\\".

This qualified name can be persisted and later used to load the Type. To search for and load a Type, use GetType either with the type name only or with the assembly qualified type name. GetType with the type name only will look for the Type in the caller's assembly and then in the System assembly. GetType with the assembly qualified type name will look for the Type in any assembly.

Type names may include trailing characters that denote additional information about the type, such as whether the type is a reference type, a pointer type or an array type. To retrieve the type name without these trailing characters, use `t.GetElementType().ToString()`, where `t` is the type.

Spaces are relevant in all type name components except the assembly name. In the assembly name, spaces before the ',' separator are relevant, but spaces after the ',' separator are ignored.

The name of a generic type ends with a backtick (`) followed by digits representing the number of generic type arguments. The purpose of this name mangling is to allow compilers to support generic types with the same name but with different numbers of type parameters, occurring in the same scope. For example, reflection returns the mangled names `Tuple`1` and `Tuple`2` from the generic methods `Tuple(Of T)` and `Tuple(Of T0, T1)` in Visual Basic, or `Tuple<T>` and `Tuple<T0, T1>` in Visual C#.

For generic types, the type argument list is enclosed in brackets, and the type arguments are separated by commas. For example, a generic Dictionary<TKey,TValue> has two type parameters. A Dictionary<TKey,TValue> of `MyType` with keys of type String might be represented as follows:

```
System.Collections.Generic.Dictionary`2[System.String,MyType]
```

To specify an assembly-qualified type within a type argument list, enclose the assembly-qualified type within brackets. Otherwise, the commas that separate the parts of the assembly-qualified name are interpreted as delimiting additional type arguments. For example, a Dictionary<TKey,TValue> of `MyType` from MyAssembly.dll, with keys of type String, might be specified as follows:

```
Type.GetType("System.Collections.Generic.Dictionary`2[System.String,
[MyType,MyAssembly]]")
```

> **Note**
>
> An assembly-qualified type can be enclosed in brackets only when it appears within a type parameter list. The rules for searching assemblies for qualified and unqualified types in type parameter lists are the same as the rules for qualified and unqualified nongeneric types.

Nullable types are a special case of generic types. For example, a nullable Int32 is represented by the string "System.Nullable`1[System.Int32]".

> **Note**
>
> In C#, C++, and Visual Basic you can also get nullable types using type operators. For example, the nullable **Boolean** type is returned by `typeof(Nullable<bool>)` in C#, by `Nullable<Boolean>::typeid` in C++, and by `GetType(Nullable(Of Boolean))` in Visual Basic.

The following table shows the syntax you use with `GetType` for various types.

Expand table

To Get	Use
A nullable Int32	`Type.GetType("System.Nullable`1[System.Int32]")`
An unmanaged pointer to `MyType`	`Type.GetType("MyType*")`
An unmanaged pointer to a pointer to `MyType`	`Type.GetType("MyType**")`
A managed pointer or reference to `MyType`	`Type.GetType("MyType&")`. Note that unlike pointers, references are limited to one level.
A parent class and a	`Type.GetType("MyParentClass+MyNestedClass")`

To Get	Use

GetType(String, Boolean, Boolean)

Gets the Type with the specified name, specifying whether to throw an exception if the type is not found and whether to perform a case-sensitive search.

```
C#

public static Type? GetType (string typeName, bool throwOnError, bool
ignoreCase);
```

Parameters

`typeName` String

The assembly-qualified name of the type to get. See AssemblyQualifiedName. If the type is in the currently executing assembly or in mscorlib.dll/System.Private.CoreLib.dll, it is sufficient to supply the type name qualified by its namespace.

`throwOnError` Boolean

`true` to throw an exception if the type cannot be found; `false` to return `null`. Specifying `false` also suppresses some other exception conditions, but not all of them. See the Exceptions section.

`ignoreCase` Boolean

`true` to perform a case-insensitive search for `typeName`, `false` to perform a case-sensitive search for `typeName`.

Returns

Type

The type with the specified name. If the type is not found, the `throwOnError` parameter specifies whether `null` is returned or an exception is thrown. In some cases, an exception is thrown regardless of the value of `throwOnError`. See the Exceptions section.

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

TypeLoadException

`throwOnError` is `true` and the type is not found.

-or-

`throwOnError` is `true` and `typeName` contains invalid characters, such as an embedded tab.

-or-

`throwOnError` is `true` and `typeName` is an empty string.

-or-

`throwOnError` is `true` and `typeName` represents an array type with an invalid size.

-or-

`typeName` represents an array of TypedReference.

ArgumentException

`throwOnError` is `true` and `typeName` contains invalid syntax. For example, "MyType[,*,]".

-or-

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

FileNotFoundException

`throwOnError` is `true` and the assembly or one of its dependencies was not found.

FileLoadException

The assembly or one of its dependencies was found, but could not be loaded.

BadImageFormatException
The assembly or one of its dependencies is not valid.

-or-

Version 2.0 or later of the common language runtime is currently loaded, and the assembly was compiled with a later version.

Remarks

You can use the GetType method to obtain a Type object for a type in another assembly if you know its assembly-qualified name, which can be obtained from AssemblyQualifiedName. GetType causes loading of the assembly specified in `typeName`. You can also load an assembly using the Assembly.Load method, and then use the Assembly.GetType or Assembly.GetTypes method to get Type objects. If a type is in an assembly known to your program at compile time, it is more efficient to use `typeof` in C# or the `GetType` operator in Visual Basic.

`GetType` only works on assemblies loaded from disk. If you call `GetType` to look up a type defined in a dynamic assembly defined using the System.Reflection.Emit services, you might get inconsistent behavior. The behavior depends on whether the dynamic assembly is persistent, that is, created using the `RunAndSave` or `Save` access modes of the System.Reflection.Emit.AssemblyBuilderAccess enumeration. If the dynamic assembly is persistent and has been written to disk before `GetType` is called, the loader finds the saved assembly on disk, loads that assembly, and retrieves the type from that assembly. If the assembly has not been saved to disk when `GetType` is called, the method returns `null`. `GetType` does not understand transient dynamic assemblies; therefore, calling `GetType` to retrieve a type in a transient dynamic assembly returns `null`.

To use `GetType` on a dynamic module, subscribe to the AppDomain.AssemblyResolve event and call `GetType` before saving. Otherwise, you will get two copies of the assembly in memory.

The `throwOnError` parameter specifies what happens when the type is not found, and also suppresses certain other exception conditions, as described in the Exceptions section. Some exceptions are thrown regardless of the value of `throwOnError`. For example, if the type is found but cannot be loaded, a TypeLoadException is thrown even if `throwOnError` is `false`.

The following table shows what members of a base class are returned by the `Get` methods when reflecting on a type.

Expand table

Member Type	Static	Non-Static
Constructor	No	No
Field	No	Yes. A field is always hide-by-name-and-signature.
Event	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.
Method	No	Yes. A method (both virtual and non-virtual) can be hide-by-name or hide-by-name-and-signature.
Nested Type	No	No
Property	Not applicable	The common type system rule is that the inheritance is the same as that of the methods that implement the property. Reflection treats properties as hide-by-name-and-signature. See note 2 below.

1. Hide-by-name-and-signature considers all of the parts of the signature, including custom modifiers, return types, parameter types, sentinels, and unmanaged calling conventions. This is a binary comparison.

2. For reflection, properties and events are hide-by-name-and-signature. If you have a property with both a get and a set accessor in the base class, but the derived class has only a get accessor, the derived class property hides the base class property, and you will not be able to access the setter on the base class.

3. Custom attributes are not part of the common type system.

Arrays or COM types are not searched for unless they have already been loaded into the table of available classes.

`typeName` can be the type name qualified by its namespace or an assembly-qualified name that includes an assembly name specification. See AssemblyQualifiedName.

If `typeName` includes the namespace but not the assembly name, this method searches only the calling object's assembly and mscorlib.dll/System.Private.CoreLib.dll, in that order. If typeName is fully qualified

with the partial or complete assembly name, this method searches in the specified assembly. If the assembly has a strong name, a complete assembly name is required.

The AssemblyQualifiedName property returns a fully qualified type name including nested types, the assembly name, and type arguments. All compilers that support the common language runtime will emit the simple name of a nested class, and reflection constructs a mangled name when queried, in accordance with the following conventions.

> **Note**
>
> In the .NET Framework version 2.0, processor architecture is added to assembly identity, and can be specified as part of assembly name strings. For example, "ProcessorArchitecture=msil". However, it is not included in the string returned by the **AssemblyQualifiedName** property, for compatibility reasons. You can also load types by creating an **AssemblyName** object and passing it to an appropriate overload of the **Load** method. You can then use the **Assembly.GetType** method to load types from the assembly. See also **AssemblyName.ProcessorArchitecture**.

Expand table

Delimiter	Meaning
Backslash (\)	Escape character.
Backtick (`)	Precedes one or more digits representing the number of type parameters, located at the end of the name of a generic type.
Brackets ([])	Enclose a generic type argument list, for a constructed generic type; within a type argument list, enclose an assembly-qualified type.
Comma (,)	Precedes the Assembly name.
Period (.)	Denotes namespace identifiers.
Plus sign (+)	Precedes a nested class.

For example, the fully qualified name for a class might look like this:

```
TopNamespace.SubNameSpace.ContainingClass+NestedClass,MyAssembly
```

If the namespace were TopNamespace.Sub+Namespace, then the string would have to precede the plus sign (+) with an escape character (\) to prevent it from being interpreted as a nesting separator. Reflection emits this string as follows:

```

TopNamespace.Sub\+Namespace.ContainingClass+NestedClass,MyAssembly
```

A "++" becomes "\+\+", and a "\" becomes "\\".

This qualified name can be persisted and later used to load the Type. To search for and load a Type, use GetType either with the type name only or with the assembly qualified type name. GetType with the type name only will look for the Type in the caller's assembly and then in the System assembly. GetType with the assembly qualified type name will look for the Type in any assembly.

Type names may include trailing characters that denote additional information about the type, such as whether the type is a reference type, a pointer type or an array type. To retrieve the type name without these trailing characters, use `t.GetElementType().ToString()`, where `t` is the type.

Spaces are relevant in all type name components except the assembly name. In the assembly name, spaces before the ',' separator are relevant, but spaces after the ',' separator are ignored.

The name of a generic type ends with a backtick (`) followed by digits representing the number of generic type arguments. The purpose of this name mangling is to allow compilers to support generic types with the same name but with different numbers of type parameters, occurring in the same scope. For example, reflection returns the mangled names `Tuple`1` and `Tuple`2` from the generic methods `Tuple(Of T)` and `Tuple(Of T0, T1)` in Visual Basic, or `Tuple<T>` and `Tuple<T0, T1>` in Visual C#.

For generic types, the type argument list is enclosed in brackets, and the type arguments are separated by commas. For example, a generic Dictionary<TKey,TValue> has two type parameters. A Dictionary<TKey,TValue> of `MyType` with keys of type String might be represented as follows:

```

```

```
System.Collections.Generic.Dictionary`2[System.String,MyType]
```

To specify an assembly-qualified type within a type argument list, enclose the assembly-qualified type within brackets. Otherwise, the commas that separate the parts of the assembly-qualified name are interpreted as delimiting additional type arguments. For example, a Dictionary<TKey,TValue> of `MyType` from MyAssembly.dll, with keys of type String, might be specified as follows:

```
Type.GetType("System.Collections.Generic.Dictionary`2[System.String,
[MyType,MyAssembly]]")
```

> **Note**
>
> An assembly-qualified type can be enclosed in brackets only when it appears within a type parameter list. The rules for searching assemblies for qualified and unqualified types in type parameter lists are the same as the rules for qualified and unqualified nongeneric types.

Nullable types are a special case of generic types. For example, a nullable Int32 is represented by the string "System.Nullable`1[System.Int32]".

> **Note**
>
> In C#, C++, and Visual Basic you can also get nullable types using type operators. For example, the nullable **Boolean** type is returned by `typeof(Nullable<bool>)` in C#, by `Nullable<Boolean>::typeid` in C++, and by `GetType(Nullable(Of Boolean))` in Visual Basic.

The following table shows the syntax you use with `GetType` for various types.

Expand table

To Get	Use
A nullable Int32	`Type.GetType("System.Nullable`1[System.Int32]")`
An unmanaged	`Type.GetType("MyType*")`

To Get	Use
pointer to `MyType`	
An unmanaged pointer to a pointer to `MyType`	`Type.GetType("MyType**")`
A managed pointer or reference to `MyType`	`Type.GetType("MyType&")`. Note that unlike pointers, references are limited to one level.
A parent class and a nested class	`Type.GetType("MyParentClass+MyNestedClass")`
A one-dimensional array with a lower bound of 0	`Type.GetType("MyArray[]")`
A one-dimensional array with an unknown lower bound	`Type.GetType("MyArray[*]")`
An n-dimensional array	A comma (,) inside the brackets a total of n-1 times. For example, `System.Object[,,]` represents a three-dimensional `Object` array.
A two-dimensional array's array	`Type.GetType("MyArray[][]")`
A rectangular two-dimensional array with unknown lower bounds	`Type.GetType("MyArray[,]")`

To Get	Use
A generic type with one type argument	`Type.GetType("MyGenericType`1[MyType]")`
A generic type with two type arguments	`Type.GetType("MyGenericType`2[MyType,AnotherType]")`
A generic type with two assembly-qualified type arguments	`Type.GetType("MyGenericType`2[[MyType,MyAssembly],[AnotherType,AnotherAssembly]]")`
An assembly-qualified generic type with an assembly-qualified type argument	`Type.GetType("MyGenericType`1[[MyType,MyAssembly]],MyGenericTypeAssembly")`
A generic type whose type argument is a generic type with two type arguments	`Type.GetType("MyGenericType`1[AnotherGenericType`2[MyType,AnotherType]]")`

.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>)

Gets the type with the specified name, optionally providing custom methods to resolve the assembly and the type.

C#

```
public static Type? GetType (string typeName,
Func<System.Reflection.AssemblyName,System.Reflection.Assembly?>?
assemblyResolver, Func<System.Reflection.Assembly?,string,bool,Type?>?
typeResolver);
```

Parameters

`typeName` String

The name of the type to get. If the `typeResolver` parameter is provided, the type name can be any string that `typeResolver` is capable of resolving. If the `assemblyResolver` parameter is provided or if standard type resolution is used, `typeName` must be an assembly-qualified name (see AssemblyQualifiedName), unless the type is in the currently executing assembly or in mscorlib.dll/System.Private.CoreLib.dll, in which case it is sufficient to supply the type name qualified by its namespace.

`assemblyResolver` Func<AssemblyName,Assembly>

A method that locates and returns the assembly that is specified in `typeName`. The assembly name is passed to `assemblyResolver` as an AssemblyName object. If `typeName` does not contain the name of an assembly, `assemblyResolver` is not called. If `assemblyResolver` is not supplied, standard assembly resolution is performed.

Caution Do not pass methods from unknown or untrusted callers. Doing so could result in elevation of privilege for malicious code. Use only methods that you provide or that you are familiar with.

`typeResolver` Func<Assembly,String,Boolean,Type>

A method that locates and returns the type that is specified by `typeName` from the assembly that is returned by `assemblyResolver` or by standard assembly resolution. If no assembly is provided, the `typeResolver` method can provide one. The method also takes a parameter that specifies whether to perform a case-insensitive search; `false` is passed to that parameter.

Caution Do not pass methods from unknown or untrusted callers.

Returns

Type

The type with the specified name, or `null` if the type is not found.

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

ArgumentException

An error occurs when `typeName` is parsed into a type name and an assembly name (for example, when the simple type name includes an unescaped special character).

-or-

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

TypeLoadException
`typeName` represents an array of TypedReference.

FileLoadException
The assembly or one of its dependencies was found, but could not be loaded.

-or-

`typeName` contains an invalid assembly name.

-or-

`typeName` is a valid assembly name without a type name.

BadImageFormatException
The assembly or one of its dependencies is not valid.

-or-

The assembly was compiled with a later version of the common language runtime than the version that is currently loaded.

Remarks

Usage scenarios for this method and details about the `assemblyResolver` and `typeResolver` parameters can be found in the GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean) method overload.

> **Note**
>
> If `typeName` cannot be found, the call to the **GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>)** method returns `null`. It does not throw an exception. To control whether an

exception is thrown, call an overload of the **GetType** method that has a `throwOnError` parameter.

Calling this method overload is the same as calling the GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean) method overload and specifying `false` for the `throwOnError` and `ignoreCase` parameters.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean)

Gets the type with the specified name, specifying whether to throw an exception if the type is not found, and optionally providing custom methods to resolve the assembly and the type.

C#

```
public static Type? GetType (string typeName,
Func<System.Reflection.AssemblyName,System.Reflection.Assembly?>?
assemblyResolver, Func<System.Reflection.Assembly?,string,bool,Type?>?
typeResolver, bool throwOnError);
```

Parameters

`typeName` String

The name of the type to get. If the `typeResolver` parameter is provided, the type name can be any string that `typeResolver` is capable of resolving. If the

`assemblyResolver` parameter is provided or if standard type resolution is used, `typeName` must be an assembly-qualified name (see AssemblyQualifiedName), unless the type is in the currently executing assembly or in mscorlib.dll/System.Private.CoreLib.dll, in which case it is sufficient to supply the type name qualified by its namespace.

`assemblyResolver` Func<AssemblyName,Assembly>

A method that locates and returns the assembly that is specified in `typeName`. The assembly name is passed to `assemblyResolver` as an AssemblyName object. If `typeName` does not contain the name of an assembly, `assemblyResolver` is not called. If `assemblyResolver` is not supplied, standard assembly resolution is performed.

Caution Do not pass methods from unknown or untrusted callers. Doing so could result in elevation of privilege for malicious code. Use only methods that you provide or that you are familiar with.

`typeResolver` Func<Assembly,String,Boolean,Type>

A method that locates and returns the type that is specified by `typeName` from the assembly that is returned by `assemblyResolver` or by standard assembly resolution. If no assembly is provided, the method can provide one. The method also takes a parameter that specifies whether to perform a case-insensitive search; `false` is passed to that parameter.

Caution Do not pass methods from unknown or untrusted callers.

`throwOnError` Boolean

`true` to throw an exception if the type cannot be found; `false` to return `null`. Specifying `false` also suppresses some other exception conditions, but not all of them. See the Exceptions section.

Returns

Type

The type with the specified name. If the type is not found, the `throwOnError` parameter specifies whether `null` is returned or an exception is thrown. In some cases, an exception is thrown regardless of the value of `throwOnError`. See the Exceptions section.

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

TypeLoadException

`throwOnError` is `true` and the type is not found.

-or-

`throwOnError` is `true` and `typeName` contains invalid characters, such as an embedded tab.

-or-

`throwOnError` is `true` and `typeName` is an empty string.

-or-

`throwOnError` is `true` and `typeName` represents an array type with an invalid size.

-or-

`typeName` represents an array of TypedReference.

ArgumentException

An error occurs when `typeName` is parsed into a type name and an assembly name (for example, when the simple type name includes an unescaped special character).

-or-

`throwOnError` is `true` and `typeName` contains invalid syntax (for example, "MyType[,*,]").

-or-

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

FileNotFoundException
`throwOnError` is `true` and the assembly or one of its dependencies was not found.

-or-

`typeName` contains an invalid assembly name.

-or-

`typeName` is a valid assembly name without a type name.

FileLoadException
The assembly or one of its dependencies was found, but could not be loaded.

BadImageFormatException
The assembly or one of its dependencies is not valid.

-or-

The assembly was compiled with a later version of the common language runtime than the version that is currently loaded.

Remarks

Usage scenarios for this method and details about the `assemblyResolver` and `typeResolver` parameters can be found in the GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean) method overload.

Calling this method overload is the same as calling the GetType(String, Func<AssemblyName,Assembly>, Func<Assembly,String,Boolean,Type>, Boolean, Boolean) method overload and specifying `false` for the `ignoreCase` parameter.

Type.GetTypeArray(Object[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the types of the objects in the specified array.

C#

```
public static Type[] GetTypeArray (object[] args);
```

Parameters

`args` Object[]

An array of objects whose types to determine.

Returns

Type[]

An array of Type objects representing the types of the corresponding elements in `args`.

Exceptions

ArgumentNullException

`args` is `null`.

-or-

One or more of the elements in `args` is `null`.

TargetInvocationException

The class initializers are invoked and at least one throws an exception.

Examples

The following code example demonstrates how to use the GetTypeArray method to list the types of the elements of an array.

C#

```
Object[] myObject = new Object[3];
myObject[0] = 66;
myObject[1] = "puri";
myObject[2] = 33.33;
// Get the array of 'Type' class objects.
Type[] myTypeArray = Type.GetTypeArray(myObject);
Console.WriteLine("Full names of the 'Type' objects in the array are:");
for(int h = 0; h < myTypeArray.Length ; h++)
{
    Console.WriteLine(myTypeArray[h].FullName);
}
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.GetTypeCode(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the underlying type code of the specified Type.

C#

```
public static TypeCode GetTypeCode (Type? type);
```

Parameters

type Type

The type whose underlying type code to get.

Returns

TypeCode

The code of the underlying type, or Empty if `type` is `null`.

Examples

The following code example demonstrates how the TypeCode enumeration can be used. In a decision block inside the `WriteObjectInfo` method, the TypeCode of an Object parameter is examined, and an appropriate message is written to the console.

C#

```
static void WriteObjectInfo(object testObject)
{
    TypeCode    typeCode = Type.GetTypeCode( testObject.GetType() );

    switch( typeCode )
    {
        case TypeCode.Boolean:
            Console.WriteLine("Boolean: {0}", testObject);
            break;
```

```
        case TypeCode.Double:
            Console.WriteLine("Double: {0}", testObject);
            break;

        default:
            Console.WriteLine("{0}: {1}", typeCode.ToString(), testObject);
            break;
    }
}
```

Remarks

When you inherit from Type, you can change the behavior of this method by overriding the GetTypeCodeImpl method. For Enum types, the type code of the underlying integral type is returned.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.GetTypeCodeImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the underlying type code of this Type instance.

C#

```
protected virtual TypeCode GetTypeCodeImpl ();
```

Returns

TypeCode

The type code of the underlying type.

Remarks

This method provides the implementation for the `static` (in C#) or `Shared` (in Visual Basic) GetTypeCode(Type) method. When you inherit from Type, you can override this method to provide your own implementation of GetTypeCode.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.GetTypeFromCLSID Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the type associated with the specified class identifier (CLSID).

Overloads

Expand table

GetTypeFromCLSID(Guid)	Gets the type associated with the specified class identifier (CLSID).
GetTypeFromCLSID(Guid, Boolean)	Gets the type associated with the specified class identifier (CLSID), specifying whether to throw an exception if an error occurs while loading the type.
GetTypeFromCLSID(Guid, String)	Gets the type associated with the specified class identifier (CLSID) from the specified server.
GetTypeFromCLSID(Guid, String, Boolean)	Gets the type associated with the specified class identifier (CLSID) from the specified server, specifying whether to throw an exception if an error occurs while loading the type.

GetTypeFromCLSID(Guid)

Gets the type associated with the specified class identifier (CLSID).

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static Type? GetTypeFromCLSID (Guid clsid);
```

Parameters

clsid Guid

The CLSID of the type to get.

Returns

Type

`System.__ComObject` regardless of whether the CLSID is valid.

Attributes SupportedOSPlatformAttribute

Examples

The following example uses the CLSID of the Microsoft Word Application object to retrieve a COM type that represents the Microsoft Word application. It then instantiates the type by calling the Activator.CreateInstance method, and closes it by calling the Application.Quit method.

C#

```
using System;
using System.Reflection;
using System.Runtime.InteropServices;

public class Example
{
   private const string WORD_CLSID = "{000209FF-0000-0000-C000-
000000000046}";

   public static void Main()
   {
      // Start an instance of the Word application.
      var word = Type.GetTypeFromCLSID(Guid.Parse(WORD_CLSID));
      Console.WriteLine("Instantiated Type object from CLSID {0}",
                        WORD_CLSID);
      Object wordObj = Activator.CreateInstance(word);
      Console.WriteLine("Instantiated {0}",
                        wordObj.GetType().FullName);

      // Close Word.
      word.InvokeMember("Quit", BindingFlags.InvokeMethod, null,
                        wordObj, new object[] { 0, 0, false } );
   }
}
// The example displays the following output:
//    Instantiated Type object from CLSID {000209FF-0000-0000-C000-
000000000046}
//    Instantiated Microsoft.Office.Interop.Word.ApplicationClass
```

Remarks

The GetTypeFromCLSID method supports late-bound access to unmanaged COM objects from .NET Framework apps when you know the COM object's class identifier (CLSID). The class identifier for COM classes is defined in the HKEY_CLASSES_ROOT\CLSID key of the registry. You can retrieve the value of the IsCOMObject property to determine whether the type returned by this method is a COM object.

> **Tip**
>
> You can call the **GetTypeFromProgID** method for late-bound access to COM objects whose programmatic identifier (ProgID) you know.

Instantiating an unmanaged COM object from its CLSID is a two-step process:

1. Get a Type object that represents the `__ComObject` that corresponds to the CLSID by calling the GetTypeFromCLSID method.
2. Call the Activator.CreateInstance(Type) method to instantiate the COM object.

See the example for an illustration.

The GetTypeFromCLSID(Guid) overload ignores any exception that may occur when instantiating a Type object based on the `clsid` argument. Note that no exception is thrown if `clsid` is not found in the registry.

Notes to Callers

This method is intended for use when working with COM objects, not with .NET Framework objects. All managed objects, including those that are visible to COM (that is, their ComVisibleAttribute attribute is `true`) have a GUID that is returned by the GUID property. Although the method returns a Type object that corresponds to the GUID for .NET Framework objects, you can't use that Type object to create a type instance by calling the CreateInstance(Type) method, as the following example shows.

C#

```
using System;
using System.Runtime.InteropServices;

[assembly:ComVisible(true)]

// Define two classes, and assign one an explicit GUID.
[GuidAttribute("d055cba3-1f83-4bd7-ba19-e22b1b8ec3c4")]
```

```
public class ExplicitGuid
{ }

public class NoExplicitGuid
{ }

public class Example
{
   public static void Main()
   {
      Type explicitType = typeof(ExplicitGuid);
      Guid explicitGuid = explicitType.GUID;

      // Get type of ExplicitGuid from its GUID.
      Type explicitCOM = Type.GetTypeFromCLSID(explicitGuid);
      Console.WriteLine("Created {0} type from CLSID {1}",
                        explicitCOM.Name, explicitGuid);

      // Compare the two type objects.
      Console.WriteLine("{0} and {1} equal: {2}",
                        explicitType.Name, explicitCOM.Name,
                        explicitType.Equals(explicitCOM));

      // Instantiate an ExplicitGuid object.
      try {
         Object obj = Activator.CreateInstance(explicitCOM);
         Console.WriteLine("Instantiated a {0} object",
obj.GetType().Name);
      }
      catch (COMException e) {
         Console.WriteLine("COM Exception:\n{0}\n", e.Message);
      }

      Type notExplicit = typeof(NoExplicitGuid);
      Guid notExplicitGuid = notExplicit.GUID;

      // Get type of ExplicitGuid from its GUID.
      Type notExplicitCOM = Type.GetTypeFromCLSID(notExplicitGuid);
      Console.WriteLine("Created {0} type from CLSID {1}",
                        notExplicitCOM.Name, notExplicitGuid);

      // Compare the two type objects.
      Console.WriteLine("{0} and {1} equal: {2}",
                        notExplicit.Name, notExplicitCOM.Name,
                        notExplicit.Equals(notExplicitCOM));

      // Instantiate an ExplicitGuid object.
      try {
         Object obj = Activator.CreateInstance(notExplicitCOM);
         Console.WriteLine("Instantiated a {0} object",
obj.GetType().Name);
      }
      catch (COMException e) {
         Console.WriteLine("COM Exception:\n{0}\n", e.Message);
      }
```

```
    }
}
// The example displays the following output:
//       Created __ComObject type from CLSID d055cba3-1f83-4bd7-ba19-
e22b1b8ec3c4
//       ExplicitGuid and __ComObject equal: False
//       COM Exception:
//       Retrieving the COM class factory for component with CLSID
//       {D055CBA3-1F83-4BD7-BA19-E22B1B8EC3C4} failed due to the
following error:
//       80040154 Class not registered
//       (Exception from HRESULT: 0x80040154 (REGDB_E_CLASSNOTREG)).
//
//       Created __ComObject type from CLSID 74f03346-a718-3516-ac78-
f351c7459ffb
//       NoExplicitGuid and __ComObject equal: False
//       COM Exception:
//       Retrieving the COM class factory for component with CLSID
//       {74F03346-A718-3516-AC78-F351C7459FFB} failed due to the
following error:
//       80040154 Class not registered
//       (Exception from HRESULT: 0x80040154 (REGDB_E_CLASSNOTREG)).
```

Instead, the GetTypeFromCLSID(Guid, String, Boolean) should only be used to retrieve the GUID of an unmanaged COM object, and the resulting Type object that is passed to the CreateInstance(Type) method must represent an unmanaged COM object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

.NET Standard	2.0, 2.1

GetTypeFromCLSID(Guid, Boolean)

Gets the type associated with the specified class identifier (CLSID), specifying whether to throw an exception if an error occurs while loading the type.

```
C#
```

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static Type? GetTypeFromCLSID (Guid clsid, bool throwOnError);
```

Parameters

`clsid` Guid

The CLSID of the type to get.

`throwOnError` Boolean

`true` to throw any exception that occurs.

-or-

`false` to ignore any exception that occurs.

Returns

Type

`System.__ComObject` regardless of whether the CLSID is valid.

Attributes SupportedOSPlatformAttribute

Examples

The following example uses the CLSID of the Microsoft Word Application object to retrieve a COM type that represents the Microsoft Word application. It then instantiates the type by calling the Activator.CreateInstance method, and closes it by calling the Application.Quit method. An exception is thrown if an error occurs while loading the type.

C#

```
using System;
using System.Reflection;
using System.Runtime.InteropServices;

public class Example
{
   private const string WORD_CLSID = "{000209FF-0000-0000-C000-
000000000046}";

   public static void Main()
   {
```

```
        try {
           // Start an instance of the Word application.
           var word = Type.GetTypeFromCLSID(Guid.Parse(WORD_CLSID), true);
           Console.WriteLine("Instantiated Type object from CLSID {0}",
                             WORD_CLSID);
           Object wordObj = Activator.CreateInstance(word);
           Console.WriteLine("Instantiated {0}",
                             wordObj.GetType().FullName, WORD_CLSID);

           // Close Word.
           word.InvokeMember("Quit", BindingFlags.InvokeMethod, null,
                             wordObj, new object[] { 0, 0, false } );
        }
        catch (Exception) {
           Console.WriteLine("Unable to instantiate an object for {0}",
WORD_CLSID);
        }
    }
}
// The example displays the following output:
//    Instantiated Type object from CLSID {000209FF-0000-0000-C000-
000000000046}
//    Instantiated Microsoft.Office.Interop.Word.ApplicationClass
```

Remarks

The GetTypeFromCLSID method supports late-bound access to unmanaged COM objects from .NET Framework apps when you know the COM object's class identifier (CLSID). The class identifier for COM classes is defined in the HKEY_CLASSES_ROOT\CLSID key of the registry. You can retrieve the value of the IsCOMObject property to determine whether the type returned by this method is a COM object.

> **Tip**
>
> You can call the **GetTypeFromProgID** method for late-bound access to COM objects whose programmatic identifier (ProgID) you know.

Instantiating an unmanaged COM object from its CLSID is a two-step process:

1. Get a Type object that represents the `__ComObject` that corresponds to the CLSID by calling the GetTypeFromCLSID method.

2. Call the Activator.CreateInstance(Type) method to instantiate the COM object.

See the example for an illustration.

Exceptions such as OutOfMemoryException will be thrown when specifying `true` for `throwOnError`, but it will not fail for unregistered CLSIDs.

Notes to Callers

This method is intended for use when working with COM objects, not with .NET Framework objects. All managed objects, including those that are visible to COM (that is, their ComVisibleAttribute attribute is `true`) have a GUID that is returned by the GUID property. Although the method returns a Type object that corresponds to the GUID for .NET Framework objects, you can't use that Type object to create a type instance by calling the CreateInstance(Type) method, as the following example shows.

C#

```
using System;
using System.Runtime.InteropServices;

[assembly:ComVisible(true)]

// Define two classes, and assign one an explicit GUID.
[GuidAttribute("d055cba3-1f83-4bd7-ba19-e22b1b8ec3c4")]
public class ExplicitGuid
{ }

public class NoExplicitGuid
{ }

public class Example
{
   public static void Main()
   {
      Type explicitType = typeof(ExplicitGuid);
      Guid explicitGuid = explicitType.GUID;

      // Get type of ExplicitGuid from its GUID.
      Type explicitCOM = Type.GetTypeFromCLSID(explicitGuid);
      Console.WriteLine("Created {0} type from CLSID {1}",
                        explicitCOM.Name, explicitGuid);

      // Compare the two type objects.
      Console.WriteLine("{0} and {1} equal: {2}",
                        explicitType.Name, explicitCOM.Name,
                        explicitType.Equals(explicitCOM));

      // Instantiate an ExplicitGuid object.
      try {
         Object obj = Activator.CreateInstance(explicitCOM);
         Console.WriteLine("Instantiated a {0} object",
obj.GetType().Name);
```

```
        }
        catch (COMException e) {
           Console.WriteLine("COM Exception:\n{0}\n", e.Message);
        }

        Type notExplicit = typeof(NoExplicitGuid);
        Guid notExplicitGuid = notExplicit.GUID;

        // Get type of ExplicitGuid from its GUID.
        Type notExplicitCOM = Type.GetTypeFromCLSID(notExplicitGuid);
        Console.WriteLine("Created {0} type from CLSID {1}",
                          notExplicitCOM.Name, notExplicitGuid);

        // Compare the two type objects.
        Console.WriteLine("{0} and {1} equal: {2}",
                          notExplicit.Name, notExplicitCOM.Name,
                          notExplicit.Equals(notExplicitCOM));

        // Instantiate an ExplicitGuid object.
        try {
           Object obj = Activator.CreateInstance(notExplicitCOM);
           Console.WriteLine("Instantiated a {0} object",
obj.GetType().Name);
        }
        catch (COMException e) {
           Console.WriteLine("COM Exception:\n{0}\n", e.Message);
        }
    }
}
// The example displays the following output:
//       Created __ComObject type from CLSID d055cba3-1f83-4bd7-ba19-
e22b1b8ec3c4
//       ExplicitGuid and __ComObject equal: False
//       COM Exception:
//       Retrieving the COM class factory for component with CLSID
//       {D055CBA3-1F83-4BD7-BA19-E22B1B8EC3C4} failed due to the
following error:
//       80040154 Class not registered
//       (Exception from HRESULT: 0x80040154 (REGDB_E_CLASSNOTREG)).
//
//       Created __ComObject type from CLSID 74f03346-a718-3516-ac78-
f351c7459ffb
//       NoExplicitGuid and __ComObject equal: False
//       COM Exception:
//       Retrieving the COM class factory for component with CLSID
//       {74F03346-A718-3516-AC78-F351C7459FFB} failed due to the
following error:
//       80040154 Class not registered
//       (Exception from HRESULT: 0x80040154 (REGDB_E_CLASSNOTREG)).
```

Instead, the GetTypeFromCLSID(Guid, String, Boolean) should only be used to retrieve the GUID of an unmanaged COM object, and the resulting Type object that

is passed to the CreateInstance(Type) method must represent an unmanaged COM object.

GetTypeFromCLSID(Guid, String)

Gets the type associated with the specified class identifier (CLSID) from the specified server.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static Type? GetTypeFromCLSID (Guid clsid, string? server);
```

Parameters

`clsid` Guid

The CLSID of the type to get.

`server` String

The server from which to load the type. If the server name is `null`, this method automatically reverts to the local machine.

Returns

Type

`System.__ComObject` regardless of whether the CLSID is valid.

Attributes SupportedOSPlatformAttribute

Examples

The following example uses the CLSID of the Microsoft Word Application object to retrieve a COM type that represents the Microsoft Word application from a server named computer17.central.contoso.com. It then instantiates the type by calling the Activator.CreateInstance method, and closes it by calling the Application.Quit method.

C#

```
using System;
using System.Reflection;
using System.Runtime.InteropServices;

public class Example
{
   private const string WORD_CLSID = "{000209FF-0000-0000-C000-
000000000046}";

   public static void Main()
   {
      // Start an instance of the Word application.
      var word = Type.GetTypeFromCLSID(Guid.Parse(WORD_CLSID),
"computer17.central.contoso.com");
      Console.WriteLine("Instantiated Type object from CLSID {0}",
                        WORD_CLSID);
      try {
         Object wordObj = Activator.CreateInstance(word);
         Console.WriteLine("Instantiated {0}",
                           wordObj.GetType().FullName, WORD_CLSID);

         // Close Word.
         word.InvokeMember("Quit", BindingFlags.InvokeMethod, null,
                           wordObj, new object[] { 0, 0, false } );
      }
      catch (COMException) {
         Console.WriteLine("Unable to instantiate object.");
      }
   }
}
// The example displays the following output:
//    Instantiated Type object from CLSID {000209FF-0000-0000-C000-
000000000046}
//    Instantiated Microsoft.Office.Interop.Word.ApplicationClass
```

Remarks

The GetTypeFromCLSID method supports late-bound access to unmanaged COM objects from .NET Framework apps when you know the COM object's class identifier

(CLSID). The class identifier for COM classes is defined in the HKEY_CLASSES_ROOT\CLSID key of the registry. You can retrieve the value of the IsCOMObject property to determine whether the type returned by this method is a COM object.

> **Tip**

public class Example
{
   private const string WORD_CLSID = "{000209FF-0000-0000-C000-
000000000046}";

   public static void Main()
   {
      try {
         // Start an instance of the Word application.
```

```
         var word = Type.GetTypeFromCLSID(Guid.Parse(WORD_CLSID),

"computer17.central.contoso.com",
                                          true);
         Console.WriteLine("Instantiated Type object from CLSID {0}",
                           WORD_CLSID);
         Object wordObj = Activator.CreateInstance(word);
         Console.WriteLine("Instantiated {0}",
                           wordObj.GetType().FullName, WORD_CLSID);

         // Close Word.
         word.InvokeMember("Quit", BindingFlags.InvokeMethod, null,
                           wordObj, new object[] { 0, 0, false } );
      }
      // The method can throw any of a variety of exceptions.
      catch (Exception e) {
         Console.WriteLine("{0}: Unable to instantiate an object for
{1}",
                           e.GetType().Name, WORD_CLSID);
      }
   }
}
// The example displays the following output:
//    Instantiated Type object from CLSID {000209FF-0000-0000-C000-
000000000046}
//    Instantiated Microsoft.Office.Interop.Word.ApplicationClass
```

Remarks

The GetTypeFromCLSID method supports late-bound access to unmanaged COM objects from .NET Framework apps when you know the COM object's class identifier (CLSID). The class identifier for COM classes is defined in the HKEY_CLASSES_ROOT\CLSID key of the registry. You can retrieve the value of the IsCOMObject property to determine whether the type returned by this method is a COM object.

> **Tip**
>
> You can call the **GetTypeFromProgID** method for late-bound access to COM objects whose programmatic identifier (ProgID) you know.

Instantiating an unmanaged COM object from its CLSID is a two-step process:

1. Get a Type object that represents the `__ComObject` that corresponds to the CLSID by calling the GetTypeFromCLSID method.

2. Call the Activator.CreateInstance(Type) method to instantiate the COM object.

Exceptions such as OutOfMemoryException will be thrown when specifying `true` for `throwOnError`, but it will not fail for unregistered CLSIDs.

Notes to Callers

This method is intended for use when working with COM objects, not with .NET Framework objects. All managed objects, including those that are visible to COM (that is, their ComVisibleAttribute attribute is `true`) have a GUID that is returned by the GUID property. Although the GetTypeFromCLSID(Guid, String, Boolean) method returns a Type object that corresponds to the GUID for a particular managed object, you can't use that Type object to create a type instance by calling the CreateInstance(Type) method, as the following example shows.

C#

```
using System;
using System.Runtime.InteropServices;

[assembly:ComVisible(true)]

// Define two classes, and assign one an explicit GUID.
[GuidAttribute("d055cba3-1f83-4bd7-ba19-e22b1b8ec3c4")]
public class ExplicitGuid
{ }

public class NoExplicitGuid
{ }

public class Example
{
   public static void Main()
   {
      Type explicitType = typeof(ExplicitGuid);
      Guid explicitGuid = explicitType.GUID;

      // Get type of ExplicitGuid from its GUID.
      Type explicitCOM = Type.GetTypeFromCLSID(explicitGuid);
      Console.WriteLine("Created {0} type from CLSID {1}",
                        explicitCOM.Name, explicitGuid);

      // Compare the two type objects.
      Console.WriteLine("{0} and {1} equal: {2}",
                        explicitType.Name, explicitCOM.Name,
                        explicitType.Equals(explicitCOM));

      // Instantiate an ExplicitGuid object.
      try {
         Object obj = Activator.CreateInstance(explicitCOM);
         Console.WriteLine("Instantiated a {0} object",
obj.GetType().Name);
```

```
        }
        catch (COMException e) {
           Console.WriteLine("COM Exception:\n{0}\n", e.Message);
        }

        Type notExplicit = typeof(NoExplicitGuid);
        Guid notExplicitGuid = notExplicit.GUID;

        // Get type of ExplicitGuid from its GUID.
        Type notExplicitCOM = Type.GetTypeFromCLSID(notExplicitGuid);
        Console.WriteLine("Created {0} type from CLSID {1}",
                          notExplicitCOM.Name, notExplicitGuid);

        // Compare the two type objects.
        Console.WriteLine("{0} and {1} equal: {2}",
                          notExplicit.Name, notExplicitCOM.Name,
                          notExplicit.Equals(notExplicitCOM));

        // Instantiate an ExplicitGuid object.
        try {
           Object obj = Activator.CreateInstance(notExplicitCOM);
           Console.WriteLine("Instantiated a {0} object",
obj.GetType().Name);
        }
        catch (COMException e) {
           Console.WriteLine("COM Exception:\n{0}\n", e.Message);
        }
    }
}
// The example displays the following output:
//       Created __ComObject type from CLSID d055cba3-1f83-4bd7-ba19-
e22b1b8ec3c4
//       ExplicitGuid and __ComObject equal: False
//       COM Exception:
//       Retrieving the COM class factory for component with CLSID
//       {D055CBA3-1F83-4BD7-BA19-E22B1B8EC3C4} failed due to the
following error:
//       80040154 Class not registered
//       (Exception from HRESULT: 0x80040154 (REGDB_E_CLASSNOTREG)).
//
//       Created __ComObject type from CLSID 74f03346-a718-3516-ac78-
f351c7459ffb
//       NoExplicitGuid and __ComObject equal: False
//       COM Exception:
//       Retrieving the COM class factory for component with CLSID
//       {74F03346-A718-3516-AC78-F351C7459FFB} failed due to the
following error:
//       80040154 Class not registered
//       (Exception from HRESULT: 0x80040154 (REGDB_E_CLASSNOTREG)).
```

Instead, the GetTypeFromCLSID(Guid, String, Boolean) should only be used to retrieve the GUID of an unmanaged COM object, and the resulting Type object that

is passed to the CreateInstance(Type) method must represent an unmanaged COM object.

Type.GetTypeFromHandle(RuntimeTypeHandle) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the type referenced by the specified type handle.

C#

```
public static Type? GetTypeFromHandle (RuntimeTypeHandle handle);
```

Parameters

`handle` RuntimeTypeHandle

The object that refers to the type.

Returns

Type

The type referenced by the specified RuntimeTypeHandle, or `null` if the Value property of `handle` is `null`.

Exceptions

TargetInvocationException

A class initializer is invoked and throws an exception.

Examples

The following example uses the GetTypeFromHandle method to get a Type object from a RuntimeTypeHandle provided by the GetTypeHandle method.

C#

```
MyClass1 myClass1 = new MyClass1();
 // Get the type referenced by the specified type handle.
Type myClass1Type = Type.GetTypeFromHandle(Type.GetTypeHandle(myClass1));
Console.WriteLine("The Names of the Attributes :"+myClass1Type.Attributes);
```

Remarks

The handles are valid only in the application domain in which they were obtained.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Type.GetTypeFromProgID Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the type associated with the specified program identifier (ProgID).

Overloads

Expand table

GetTypeFromProgID(String)	Gets the type associated with the specified program identifier (ProgID), returning null if an error is encountered while loading the Type.
GetTypeFromProgID(String, Boolean)	Gets the type associated with the specified program identifier (ProgID), specifying whether to throw an exception if an error occurs while loading the type.
GetTypeFromProgID(String, String)	Gets the type associated with the specified program identifier (progID) from the specified server, returning null if an error is encountered while loading the type.
GetTypeFromProgID(String, String, Boolean)	Gets the type associated with the specified program identifier (progID) from the specified server, specifying whether to throw an exception if an error occurs while loading the type.

GetTypeFromProgID(String)

Gets the type associated with the specified program identifier (ProgID), returning null if an error is encountered while loading the Type.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static Type? GetTypeFromProgID (string progID);
```

Parameters

`progID` String

The ProgID of the type to get.

Returns

Type

The type associated with the specified ProgID, if `progID` is a valid entry in the registry and a type is associated with it; otherwise, `null`.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentException

`progID` is `null`.

Remarks

This method is provided for COM support. ProgIDs are not used in the Microsoft .NET Framework because they have been superseded by the concept of namespace.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

GetTypeFromProgID(String, Boolean)

Gets the type associated with the specified program identifier (ProgID), specifying whether to throw an exception if an error occurs while loading the type.

```
C#

[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static Type? GetTypeFromProgID (string progID, bool throwOnError);
```

Parameters

progID String

The ProgID of the type to get.

throwOnError Boolean

`true` to throw any exception that occurs.

-or-

`false` to ignore any exception that occurs.

Returns

Type

The type associated with the specified program identifier (ProgID), if `progID` is a valid entry in the registry and a type is associated with it; otherwise, `null`.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentException

`progID` is `null`.

COMException

The specified ProgID is not registered.

Examples

The following example retrieves a type by passing a ProgID, specifying whether to throw an exception if the ProgID is invalid. The example then displays the ClassID related to the ProgID, along with any applicable exception message.

C#

```
using System;
class MainApp
{
    public static void Main()
    {
        try
        {
            // Use the ProgID HKEY_CLASSES_ROOT\DirControl.DirList.1.
            string myString1 ="DIRECT.ddPalette.3";
            // Use a nonexistent ProgID WrongProgID.
            string myString2 ="WrongProgID";
            // Make a call to the method to get the type information of
the given ProgID.
            Type myType1 =Type.GetTypeFromProgID(myString1,true);
            Console.WriteLine("GUID for ProgID DirControl.DirList.1 is
{0}.", myType1.GUID);
            // Throw an exception because the ProgID is invalid and the
throwOnError
            // parameter is set to True.
            Type myType2 =Type.GetTypeFromProgID(myString2,true);
        }
        catch(Exception e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Source: {0}", e.Source);
            Console.WriteLine("Message: {0}", e.Message);
        }
    }
}
```

Remarks

This method is provided for COM support. Program IDs are not used in Microsoft .NET Framework because they have been superseded by the concept of namespace.

.NET Standard	2.0, 2.1

GetTypeFromProgID(String, String)

Gets the type associated with the specified program identifier (progID) from the specified server, returning null if an error is encountered while loading the type.

C#

```
[System.Runtime.Versioning.SupportedOSPlatform("windows")]
public static Type? GetTypeFromProgID (string progID, string? server);
```

Parameters

progID String

The progID of the type to get.

server String

The server from which to load the type. If the server name is `null`, this method automatically reverts to the local machine.

Returns

Type

The type associated with the specified program identifier (progID), if `progID` is a valid entry in the registry and a type is associated with it; otherwise, `null`.

Attributes SupportedOSPlatformAttribute

Exceptions

ArgumentException

`prodID` is `null`.

Examples

The following example retrieves a type by passing a ProgID and server name. The example then displays the ClassID related to the ProgID, or throws an exception if the ProgID or the server name is invalid.

C#

```
using System;
class MainApp
{
    public static void Main()
    {
        try
        {
            // Use the ProgID
localhost\HKEY_CLASSES_ROOT\DirControl.DirList.1.
            string theProgramID ="DirControl.DirList.1";
            // Use the server name localhost.
            string theServer="localhost";
            // Make a call to the method to get the type information for
the given ProgID.
            Type myType =Type.GetTypeFromProgID(theProgramID,theServer);
            if(myType==null)
            {
                throw new Exception("Invalid ProgID or Server.");
            }
            Console.WriteLine("GUID for ProgID DirControl.DirList.1 is
{0}.", myType.GUID);
        }
        catch(Exception e)
        {
            Console.WriteLine("An exception occurred.");
            Console.WriteLine("Source: {0}" , e.Source);
            Console.WriteLine("Message: {0}" , e.Message);
        }
    }
}
```

Remarks

This method is provided for COM support. Program IDs are not used in Microsoft .NET Framework because they have been superseded by the concept of namespace.

        {
            // Use server localhost.
            string theServer="localhost";
            // Use  ProgID HKEY_CLASSES_ROOT\DirControl.DirList.1.
            string myString1 ="DirControl.DirList.1";
            // Use a wrong ProgID WrongProgID.
            string myString2 ="WrongProgID";
            // Make a call to the method to get the type information for
the given ProgID.
            Type myType1
=Type.GetTypeFromProgID(myString1,theServer,true);
            Console.WriteLine("GUID for ProgID DirControl.DirList.1 is
{0}.", myType1.GUID);
            // Throw an exception because the ProgID is invalid and the
throwOnError
            // parameter is set to True.
            Type myType2 =Type.GetTypeFromProgID(myString2, theServer,
true);
        }
        catch(Exception e)
```

```
        {
            Console.WriteLine("An exception occurred. The ProgID is
wrong.");
            Console.WriteLine("Source: {0}" , e.Source);
            Console.WriteLine("Message: {0}" , e.Message);
        }
    }
}
```

Remarks

This method is provided for COM support. Program IDs are not used in Microsoft .NET Framework because they have been superseded by the concept of namespace.

Type.GetTypeHandle(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the handle for the Type of a specified object.

C#

```
public static RuntimeTypeHandle GetTypeHandle (object o);
```

Parameters

o Object

The object for which to get the type handle.

Returns

RuntimeTypeHandle

The handle for the Type of the specified Object.

Exceptions

ArgumentNullException

`o` is `null`.

Examples

The following example defines the class `MyClass1`, gets an instance of it, and retrieves the runtime handle of the object.

C#

```
using System;
using System.Reflection;

public class MyClass1
```

```
{
    private int x=0;
    public int MyMethod()
    {
        return x;
    }
}

public class MyClass2
{
    public static void Main()
    {
        MyClass1 myClass1 = new MyClass1();

        // Get the RuntimeTypeHandle from an object.
        RuntimeTypeHandle myRTHFromObject = Type.GetTypeHandle(myClass1);
        // Get the RuntimeTypeHandle from a type.
        RuntimeTypeHandle myRTHFromType = typeof(MyClass1).TypeHandle;

        Console.WriteLine("\nmyRTHFromObject.Value:  {0}",
myRTHFromObject.Value);
        Console.WriteLine("myRTHFromObject.GetType():  {0}",
myRTHFromObject.GetType());
        Console.WriteLine("Get the type back from the handle...");
        Console.WriteLine("Type.GetTypeFromHandle(myRTHFromObject):  {0}",
            Type.GetTypeFromHandle(myRTHFromObject));

        Console.WriteLine("\nmyRTHFromObject.Equals(myRTHFromType):  {0}",
            myRTHFromObject.Equals(myRTHFromType));

        Console.WriteLine("\nmyRTHFromType.Value:  {0}",
myRTHFromType.Value);
        Console.WriteLine("myRTHFromType.GetType():  {0}",
myRTHFromType.GetType());
        Console.WriteLine("Get the type back from the handle...");
        Console.WriteLine("Type.GetTypeFromHandle(myRTHFromType):  {0}",
            Type.GetTypeFromHandle(myRTHFromType));
    }
}

/* This code example produces output similar to the following:

myRTHFromObject.Value:  799464
myRTHFromObject.GetType():  System.RuntimeTypeHandle
Get the type back from the handle...
Type.GetTypeFromHandle(myRTHFromObject):  MyClass1

myRTHFromObject.Equals(myRTHFromType):  True

myRTHFromType.Value:  799464
myRTHFromType.GetType():  System.RuntimeTypeHandle
Get the type back from the handle...
Type.GetTypeFromHandle(myRTHFromType):  MyClass1
 */
```

Remarks

The handles are valid only in the application domain in which they were obtained.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.HasElementTypeImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the HasElementType property and determines whether the current Type encompasses or refers to another type; that is, whether the current Type is an array, a pointer, or is passed by reference.

C#

```
protected abstract bool HasElementTypeImpl ();
```

Returns

Boolean

`true` if the Type is an array, a pointer, or is passed by reference; otherwise, `false`.

Examples

The following example defines the class `MyTypeDelegator`, which overrides the `HasElementTypeImpl` method. The main class checks for the `HasElementType` property and displays the element type.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegator : TypeDelegator
{
    public string myElementType = null;
    private Type myType = null ;
    public MyTypeDelegator(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override Type.HasElementTypeImpl().
    protected override bool HasElementTypeImpl()
    {
```

```
        // Determine whether the type is an array.
        if(myType.IsArray)
        {
            myElementType = "array";
            return true;
        }
        // Determine whether the type is a reference.
        if(myType.IsByRef)
        {
            myElementType = "reference";
            return true;
        }
        // Determine whether the type is a pointer.
        if(myType.IsPointer)
        {
            myElementType = "pointer";
            return true;
        }
        // Return false if the type is not a reference, array, or pointer
type.
        return false;
    }
}
public class Type_HasElementTypeImpl
{
    public static void Main()
    {
        try
        {
            int myInt = 0 ;
            int[] myArray = new int[5];
            MyTypeDelegator myType = new MyTypeDelegator(myArray.GetType());
            // Determine whether myType is an array, pointer, reference
type.
            Console.WriteLine("\nDetermine whether a variable is an array,
pointer, or reference type.\n");
            if( myType.HasElementType)
                Console.WriteLine("The type of myArray is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myArray is not an array, pointer, or
reference type.");
            myType = new MyTypeDelegator(myInt.GetType());
            // Determine whether myType is an array, pointer, reference
type.
            if( myType.HasElementType)
                Console.WriteLine("The type of myInt is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myInt is not an array, pointer, or
reference type.");
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message);
```

```
        }
    }
}
```

Remarks

For example, Type.GetType("Int32[]").HasElementTypeImpl returns `true`, but Type.GetType("Int32").HasElementTypeImpl returns `false`. HasElementTypeImpl also returns `true` for "Int32*" and "Int32&".

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.InvokeMember Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Invokes a specific member of the current Type.

Overloads

Expand table

InvokeMember(String, BindingFlags, Binder, Object, Object[])	Invokes the specified member, using the specified binding constraints and matching the specified argument list.
InvokeMember(String, BindingFlags, Binder, Object, Object[], CultureInfo)	Invokes the specified member, using the specified binding constraints and matching the specified argument list and culture.
InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[], CultureInfo, String[])	When overridden in a derived class, invokes the specified member, using the specified binding constraints and matching the specified argument list, modifiers and culture.

InvokeMember(String, BindingFlags, Binder, Object, Object[])

Invokes the specified member, using the specified binding constraints and matching the specified argument list.

C#

```
public object? InvokeMember (string name, System.Reflection.BindingFlags
invokeAttr, System.Reflection.Binder? binder, object? target, object?[]?
args);
```

Parameters

`name` String

The string containing the name of the constructor, method, property, or field member to invoke.

-or-

An empty string ("") to invoke the default member.

-or-

For `IDispatch` members, a string representing the DispID, for example "[DispID=3]".

`invokeAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted. The access can be one of the `BindingFlags` such as `Public`, `NonPublic`, `Private`, `InvokeMethod`, `GetField`, and so on. The type of lookup need not be specified. If the type of lookup is omitted, `BindingFlags.Public` | `BindingFlags.Instance` | `BindingFlags.Static` are used.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder. Note that explicitly defining a Binder object may be required for successfully invoking method overloads with variable arguments.

`target` Object

The object on which to invoke the specified member.

`args` Object[]

An array containing the arguments to pass to the member to invoke.

Returns

Object

An object representing the return value of the invoked member.

Exceptions

ArgumentNullException

`invokeAttr` does not contain `CreateInstance` and `name` is `null`.

ArgumentException

`invokeAttr` is not a valid BindingFlags attribute.

-or-

`invokeAttr` does not contain one of the following binding flags: `InvokeMethod`, `CreateInstance`, `GetField`, `SetField`, `GetProperty`, or `SetProperty`.

-or-

`invokeAttr` contains `CreateInstance` combined with `InvokeMethod`, `GetField`, `SetField`, `GetProperty`, or `SetProperty`.

-or-

`invokeAttr` contains both `GetField` and `SetField`.

-or-

`invokeAttr` contains both `GetProperty` and `SetProperty`.

-or-

`invokeAttr` contains `InvokeMethod` combined with `SetField` or `SetProperty`.

-or-

`invokeAttr` contains `SetField` and `args` has more than one element.

-or-

This method is called on a COM object and one of the following binding flags was not passed in: `BindingFlags.InvokeMethod`, `BindingFlags.GetProperty`, `BindingFlags.SetProperty`, `BindingFlags.PutDispProperty`, or `BindingFlags.PutRefDispProperty`.

-or-

One of the named parameter arrays contains a string that is `null`.

MethodAccessException

The specified member is a class initializer.

MissingFieldException

The field or property cannot be found.

MissingMethodException

No method can be found that matches the arguments in `args`.

-or-

The current Type object represents a type that contains open type parameters, that is, ContainsGenericParameters returns `true`.

TargetException

The specified member cannot be invoked on `target`.

AmbiguousMatchException

More than one method matches the binding criteria.

NotSupportedException

The .NET Compact Framework does not currently support this method.

InvalidOperationException

The method represented by `name` has one or more unspecified generic type parameters. That is, the method's ContainsGenericParameters property returns `true`.

Examples

The following example uses `InvokeMember` to access members of a type.

C#

```
using System;
using System.Reflection;

// This sample class has a field, constructor, method, and property.
class MyType
{
    Int32 myField;
    public MyType(ref Int32 x) {x *= 5;}
    public override String ToString() {return myField.ToString();}
    public Int32 MyProp
    {
        get {return myField;}
```

```
        set
        {
            if (value < 1)
                throw new ArgumentOutOfRangeException("value", value,
"value must be > 0");
            myField = value;
        }
    }
}

class MyApp
{
    static void Main()
    {
        Type t = typeof(MyType);
        // Create an instance of a type.
        Object[] args = new Object[] {8};
        Console.WriteLine("The value of x before the constructor is
called is {0}.", args[0]);
        Object obj = t.InvokeMember(null,
            BindingFlags.DeclaredOnly |
            BindingFlags.Public | BindingFlags.NonPublic |
            BindingFlags.Instance | BindingFlags.CreateInstance, null,
null, args);
        Console.WriteLine("Type: " + obj.GetType().ToString());
        Console.WriteLine("The value of x after the constructor returns
is {0}.", args[0]);

        // Read and write to a field.
        t.InvokeMember("myField",
            BindingFlags.DeclaredOnly |
            BindingFlags.Public | BindingFlags.NonPublic |
            BindingFlags.Instance | BindingFlags.SetField, null, obj, new
Object[] {5});
        Int32 v = (Int32) t.InvokeMember("myField",
            BindingFlags.DeclaredOnly |
            BindingFlags.Public | BindingFlags.NonPublic |
            BindingFlags.Instance | BindingFlags.GetField, null, obj,
null);
        Console.WriteLine("myField: " + v);

        // Call a method.
        String s = (String) t.InvokeMember("ToString",
            BindingFlags.DeclaredOnly |
            BindingFlags.Public | BindingFlags.NonPublic |
            BindingFlags.Instance | BindingFlags.InvokeMethod, null, obj,
null);
        Console.WriteLine("ToString: " + s);

        // Read and write a property. First, attempt to assign an
        // invalid value; then assign a valid value; finally, get
        // the value.
        try
        {
            // Assign the value zero to MyProp. The Property Set
```

```
            // throws an exception, because zero is an invalid value.
            // InvokeMember catches the exception, and throws
            // TargetInvocationException. To discover the real cause
            // you must catch TargetInvocationException and examine
            // the inner exception.
            t.InvokeMember("MyProp",
                BindingFlags.DeclaredOnly |
                BindingFlags.Public | BindingFlags.NonPublic |
                BindingFlags.Instance | BindingFlags.SetProperty, null,
obj, new Object[] {0});
        }
        catch (TargetInvocationException e)
        {
            // If the property assignment failed for some unexpected
            // reason, rethrow the TargetInvocationException.
            if (e.InnerException.GetType() !=
                typeof(ArgumentOutOfRangeException))
                throw;
            Console.WriteLine("An invalid value was assigned to
MyProp.");
        }
        t.InvokeMember("MyProp",
            BindingFlags.DeclaredOnly |
            BindingFlags.Public | BindingFlags.NonPublic |
            BindingFlags.Instance | BindingFlags.SetProperty, null, obj,
new Object[] {2});
        v = (Int32) t.InvokeMember("MyProp",
            BindingFlags.DeclaredOnly |
            BindingFlags.Public | BindingFlags.NonPublic |
            BindingFlags.Instance | BindingFlags.GetProperty, null, obj,
null);
        Console.WriteLine("MyProp: " + v);
    }
}
```

Remarks

> **Note**
>
> You cannot use **InvokeMember** to invoke a generic method.

The following BindingFlags filter flags can be used to define which members to include in the search:

- Specify `BindingFlags.Public` to include public members in the search.
- Specify `BindingFlags.NonPublic` to include non-public members (that is, private and protected members) in the search.

- Specify `BindingFlags.FlattenHierarchy` to include static members up the hierarchy.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

The following BindingFlags invocation flags can be used to denote what action to take with the member:

- `CreateInstance` to invoke a constructor. `name` is ignored. Not valid with other invocation flags.
- `InvokeMethod` to invoke a method, but not a constructor or a type initializer. Not valid with `SetField` or `SetProperty`. If `InvokeMethod` is specified by itself, `BindingFlags.Public`, `BindingFlags.Instance`, and `BindingFlags.Static` are automatically included.
- `GetField` to get the value of a field. Not valid with `SetField`.
- `SetField` to set the value of a field. Not valid with `GetField`.
- `GetProperty` to get a property. Not valid with `SetProperty`.
- `SetProperty` to set a property. Not valid with `GetProperty`.

See System.Reflection.BindingFlags for more information.

A method will be invoked if both of the following conditions are true:

- The number of parameters in the method declaration equals the number of arguments in the `args` array (unless default arguments are defined on the member and `BindingFlags.OptionalParamBinding` is specified).
- The type of each argument can be converted by the binder to the type of the parameter.

The binder will find all of the matching methods. These methods are found based upon the type of binding requested (BindingFlags values `InvokeMethod`, `GetProperty`, and so on). The set of methods is filtered by the name, number of arguments, and a set of search modifiers defined in the binder.

After the method is selected, it is invoked. Accessibility is checked at that point. The search may control which set of methods are searched based upon the accessibility attribute associated with the method. The Binder.BindToMethod method of the Binder class is responsible for selecting the method to be invoked. The default binder selects the most specific match.

Access restrictions are ignored for fully trusted code; that is, private constructors, methods, fields, and properties can be accessed and invoked through System.Reflection whenever the code is fully trusted.

You can use `Type.InvokeMember` to set a field to a particular value by specifying BindingFlags.SetField. For example, if you want to set a public instance field named F on class C, and F is a `String`, you can use code such as:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[]
{"strings new value"});
```

If F is a `String[]`, you can use code such as:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[] {new
String[]{"a","z","c","d"}});
```

which will initialize the field F to this new array. You can also use `Type.InvokeMember` to set a position in an array by supplying the index of the value and then the next value by using code such as the following:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[] {1,
"b"});
```

This will change string "z" in the array that F holds to string "b".

When you invoke an `IDispatch` member, you can specify the DispID instead of the member name, using the string format "[DispID=##]". For example, if the DispID of MyComMethod is 3, you can specify the string "[DispID=3]" instead of "MyComMethod". Invoking a member by DispID is faster than looking up the member by name. In complex aggregation scenarios, the DispID is sometimes the only way to invoke the desired member.

> **Note**
>
> Starting with the .NET Framework 2.0 Service Pack 1, this method can be used to access non-public members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the

grant set of the non-public members is restricted to the caller's grant set, or a subset thereof. (See **Security Considerations for Reflection**.)

To use this functionality, your application should target the .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

InvokeMember(String, BindingFlags, Binder, Object, Object[], CultureInfo)

Invokes the specified member, using the specified binding constraints and matching the specified argument list and culture.

C#

```
public object? InvokeMember (string name, System.Reflection.BindingFlags
invokeAttr, System.Reflection.Binder? binder, object? target, object?[]?
args, System.Globalization.CultureInfo? culture);
```

Parameters

`name` String

The string containing the name of the constructor, method, property, or field member to invoke.

-or-

An empty string ("") to invoke the default member.

-or-

For `IDispatch` members, a string representing the DispID, for example "[DispID=3]".

`invokeAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted. The access can be one of the `BindingFlags` such as `Public`, `NonPublic`, `Private`, `InvokeMethod`, `GetField`, and so on. The type of lookup need not be specified. If the type of lookup is omitted, `BindingFlags.Public` | `BindingFlags.Instance` | `BindingFlags.Static` are used.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (`Nothing` in Visual Basic), to use the DefaultBinder. Note that explicitly defining a Binder object may be required for successfully invoking method overloads with variable arguments.

`target` Object

The object on which to invoke the specified member.

`args` Object[]

An array containing the arguments to pass to the member to invoke.

`culture` CultureInfo

The object representing the globalization locale to use, which may be necessary for locale-specific conversions, such as converting a numeric String to a Double.

-or-

A null reference (`Nothing` in Visual Basic) to use the current thread's CultureInfo.

Returns

Object

An object representing the return value of the invoked member.

Exceptions

ArgumentNullException

`invokeAttr` does not contain `CreateInstance` and `name` is `null`.

ArgumentException

`invokeAttr` is not a valid BindingFlags attribute.

-or-

`invokeAttr` does not contain one of the following binding flags: `InvokeMethod`, `CreateInstance`, `GetField`, `SetField`, `GetProperty`, or `SetProperty`.

-or-

`invokeAttr` contains `CreateInstance` combined with `InvokeMethod`, `GetField`, `SetField`, `GetProperty`, or `SetProperty`.

-or-

`invokeAttr` contains both `GetField` and `SetField`.

-or-

`invokeAttr` contains both `GetProperty` and `SetProperty`.

-or-

`invokeAttr` contains `InvokeMethod` combined with `SetField` or `SetProperty`.

-or-

`invokeAttr` contains `SetField` and `args` has more than one element.

-or-

This method is called on a COM object and one of the following binding flags was not passed in: `BindingFlags.InvokeMethod`, `BindingFlags.GetProperty`,

`BindingFlags.SetProperty`, `BindingFlags.PutDispProperty`, or `BindingFlags.PutRefDispProperty`.

-or-

One of the named parameter arrays contains a string that is `null`.

MethodAccessException
The specified member is a class initializer.

MissingFieldException
The field or property cannot be found.

MissingMethodException
No method can be found that matches the arguments in `args`.

-or-

The current Type object represents a type that contains open type parameters, that is, ContainsGenericParameters returns `true`.

TargetException
The specified member cannot be invoked on `target`.

AmbiguousMatchException
More than one method matches the binding criteria.

InvalidOperationException
The method represented by `name` has one or more unspecified generic type parameters. That is, the method's ContainsGenericParameters property returns `true`.

Remarks

Although the default binder does not process CultureInfo (the `culture` parameter), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `culture`.

> ⓘ **Note**
>
> You cannot use **InvokeMember** to invoke a generic method.

The following BindingFlags filter flags can be used to define which members to include in the search:

- Specify `BindingFlags.Public` to include public members in the search.
- Specify `BindingFlags.NonPublic` to include non-public members (that is, private, internal, and protected members) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include static members up the hierarchy.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.
- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

The following BindingFlags invocation flags can be used to denote what action to take with the member:

- `CreateInstance` to invoke a constructor. `name` is ignored. Not valid with other invocation flags.
- `InvokeMethod` to invoke a method, but not a constructor or a type initializer. Not valid with `SetField` or `SetProperty`. If `InvokeMethod` is specified by itself, `BindingFlags.Public`, `BindingFlags.Instance`, and `BindingFlags.Static` are automatically included.
- `GetField` to get the value of a field. Not valid with `SetField`.
- `SetField` to set the value of a field. Not valid with `GetField`.
- `GetProperty` to get a property. Not valid with `SetProperty`.
- `SetProperty` to set a property. Not valid with `GetProperty`.

See System.Reflection.BindingFlags for more information.

A method will be invoked if both of the following conditions are true:

- The number of parameters in the method declaration equals the number of arguments in the `args` array (unless default arguments are defined on the member and `BindingFlags.OptionalParamBinding` is specified).

- The type of each argument can be converted by the binder to the type of the parameter.

The binder will find all of the matching methods. These methods are found based upon the type of binding requested (BindingFlags values `InvokeMethod`, `GetProperty`, and so on). The set of methods is filtered by the name, number of arguments, and a set of search modifiers defined in the binder.

After the method is selected, it is invoked. Accessibility is checked at that point. The search may control which set of methods are searched based upon the accessibility attribute associated with the method. The Binder.BindToMethod method of the Binder class is responsible for selecting the method to be invoked. The default binder selects the most specific match.

Access restrictions are ignored for fully trusted code; that is, private constructors, methods, fields, and properties can be accessed and invoked through Reflection whenever the code is fully trusted.

You can use `Type.InvokeMember` to set a field to a particular value by specifying BindingFlags.SetField. For example, if you want to set a public instance field named F on class C, and F is a `String` you can use code such as:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[]
{"strings new value"}, null);
```

If F is a `String[]`, you can use code such as:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[] {new
String[]{"a","z","c","d"}}, null);
```

which will initialize the field F to this new array. You can also use `Type.InvokeMember` to set a position in an array by supplying the index of the value and then the next value by using code such as the following:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[] {1,
"b"}, null);
```

This will change string "z" in the array that F holds to string "b".

When you invoke an `IDispatch` member you can specify the DispID instead of the member name, using the string format "[DispID=##]". For example, if the DispID of MyComMethod is 3, you can specify the string "[DispID=3]" instead of "MyComMethod". Invoking a member by DispID is faster than looking up the

member by name. In complex aggregation scenarios, the DispID is sometimes the only way to invoke the desired member.

> **Note**
>
> Starting with the .NET Framework 2.0 Service Pack 1, this method can be used to access non-public members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the non-public members is restricted to the caller's grant set, or a subset thereof. (See **Security Considerations for Reflection**.)
>
> To use this functionality, your application should target the .NET Framework 3.5 or later.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[],

CultureInfo, String[])

When overridden in a derived class, invokes the specified member, using the specified binding constraints and matching the specified argument list, modifiers and culture.

```
C#

public abstract object? InvokeMember (string name,
System.Reflection.BindingFlags invokeAttr, System.Reflection.Binder?
binder, object? target, object?[]? args,
System.Reflection.ParameterModifier[]? modifiers,
System.Globalization.CultureInfo? culture, string[]? namedParameters);
```

Parameters

`name` String

The string containing the name of the constructor, method, property, or field member to invoke.

-or-

An empty string ("") to invoke the default member.

-or-

For `IDispatch` members, a string representing the DispID, for example "[DispID=3]".

`invokeAttr` BindingFlags

A bitwise combination of the enumeration values that specify how the search is conducted. The access can be one of the `BindingFlags` such as `Public`, `NonPublic`, `Private`, `InvokeMethod`, `GetField`, and so on. The type of lookup need not be specified. If the type of lookup is omitted, `BindingFlags.Public` | `BindingFlags.Instance` | `BindingFlags.Static` are used.

`binder` Binder

An object that defines a set of properties and enables binding, which can involve selection of an overloaded method, coercion of argument types, and invocation of a member through reflection.

-or-

A null reference (Nothing in Visual Basic), to use the DefaultBinder. Note that explicitly defining a Binder object may be required for successfully invoking method overloads with variable arguments.

`target` Object

The object on which to invoke the specified member.

`args` Object[]

An array containing the arguments to pass to the member to invoke.

`modifiers` ParameterModifier[]

An array of ParameterModifier objects representing the attributes associated with the corresponding element in the `args` array. A parameter's associated attributes are stored in the member's signature.

The default binder processes this parameter only when calling a COM component.

`culture` CultureInfo

The CultureInfo object representing the globalization locale to use, which may be necessary for locale-specific conversions, such as converting a numeric String to a Double.

-or-

A null reference (`Nothing` in Visual Basic) to use the current thread's CultureInfo.

`namedParameters` String[]

An array containing the names of the parameters to which the values in the `args` array are passed.

Returns

Object

An object representing the return value of the invoked member.

Implements

InvokeMember(String, BindingFlags, Binder, Object, Object[], ParameterModifier[], CultureInfo, String[])

Exceptions

ArgumentNullException

`invokeAttr` does not contain `CreateInstance` and `name` is `null`.

ArgumentException

`args` and `modifiers` do not have the same length.

-or-

`invokeAttr` is not a valid BindingFlags attribute.

-or-

`invokeAttr` does not contain one of the following binding flags: `InvokeMethod`, `CreateInstance`, `GetField`, `SetField`, `GetProperty`, or `SetProperty`.

-or-

`invokeAttr` contains `CreateInstance` combined with `InvokeMethod`, `GetField`, `SetField`, `GetProperty`, or `SetProperty`.

-or-

`invokeAttr` contains both `GetField` and `SetField`.

-or-

`invokeAttr` contains both `GetProperty` and `SetProperty`.

-or-

`invokeAttr` contains `InvokeMethod` combined with `SetField` or `SetProperty`.

-or-

`invokeAttr` contains `SetField` and `args` has more than one element.

-or-

The named parameter array is larger than the argument array.

-or-

This method is called on a COM object and one of the following binding flags was not passed in: `BindingFlags.InvokeMethod`, `BindingFlags.GetProperty`,

`BindingFlags.SetProperty`, `BindingFlags.PutDispProperty`, or `BindingFlags.PutRefDispProperty`.

-or-

One of the named parameter arrays contains a string that is `null`.

MethodAccessException
The specified member is a class initializer.

MissingFieldException
The field or property cannot be found.

MissingMethodException
No method can be found that matches the arguments in `args`.

-or-

No member can be found that has the argument names supplied in `namedParameters`.

-or-

The current Type object represents a type that contains open type parameters, that is, ContainsGenericParameters returns `true`.

TargetException
The specified member cannot be invoked on `target`.

AmbiguousMatchException
More than one method matches the binding criteria.

InvalidOperationException
The method represented by `name` has one or more unspecified generic type parameters. That is, the method's ContainsGenericParameters property returns `true`.

Remarks

`InvokeMember` calls a constructor member or a method member, gets or sets a property member, gets or sets a data field member, or gets or sets an element of an array member.

> **Note**
>
> You cannot use **InvokeMember** to invoke a generic method.

When you invoke an `IDispatch` member you can specify the DispID instead of the member name, using the string format "[DispID=##]". For example, if the DispID of MyComMethod is 3, you can specify the string "[DispID=3]" instead of "MyComMethod". Invoking a member by DispID is faster than looking up the member by name. In complex aggregation scenarios, the DispID is sometimes the only way to invoke the desired member.

Although the default binder does not process ParameterModifier or CultureInfo (the `modifiers` and `culture` parameters), you can use the abstract System.Reflection.Binder class to write a custom binder that does process `modifiers` and `culture`. `ParameterModifier` is only used when calling through COM interop, and only parameters that are passed by reference are handled.

Each parameter in the `namedParameters` array gets the value in the corresponding element in the `args` array. If the length of `args` is greater than the length of `namedParameters`, the remaining argument values are passed in order.

The `namedParameters` array can be used to change the order of arguments in an input array. For example, given the method `M(string a, int b)` (`M(ByVal a As String, ByVal b As Integer)` in Visual Basic) and the input array `{ 42, "x" }`, the input array can be passed unchanged to `args` if the array `{ "b", "a" }` is supplied for `namedParameters`.

The following BindingFlags filter flags can be used to define which members to include in the search:

- Specify `BindingFlags.Public` to include public members in the search.
- Specify `BindingFlags.NonPublic` to include non-public members (that is, private, internal, and protected members) in the search.
- Specify `BindingFlags.FlattenHierarchy` to include static members up the hierarchy.

The following BindingFlags modifier flags can be used to change how the search works:

- `BindingFlags.IgnoreCase` to ignore the case of `name`.

- `BindingFlags.DeclaredOnly` to search only the members declared on the Type, not members that were simply inherited.

The following BindingFlags invocation flags can be used to denote what action to take with the member:

- `CreateInstance` to invoke a constructor. `name` is ignored. Not valid with other invocation flags.
- `InvokeMethod` to invoke a method, but not a constructor or a type initializer. Not valid with `SetField` or `SetProperty`. If `InvokeMethod` is specified by itself, `BindingFlags.Public`, `BindingFlags.Instance`, and `BindingFlags.Static` are automatically included.
- `GetField` to get the value of a field. Not valid with `SetField`.
- `SetField` to set the value of a field. Not valid with `GetField`.
- `GetProperty` to get a property. Not valid with `SetProperty`.
- `SetProperty` to set a property. Not valid with `GetProperty`.

See System.Reflection.BindingFlags for more information.

A method will be invoked if both of the following conditions are true:

- The number of parameters in the method declaration equals the number of arguments in the `args` array (unless default arguments are defined on the member and `BindingFlags.OptionalParamBinding` is specified).
- The type of each argument can be converted by the binder to the type of the parameter.

The binder will find all of the matching methods. These methods are found based upon the type of binding requested (BindingFlags values `InvokeMethod`, `GetProperty`, and so on). The set of methods is filtered by the name, number of arguments, and a set of search modifiers defined in the binder.

After the method is selected, it is invoked. Accessibility is checked at that point. The search may control which set of methods are searched based upon the accessibility attribute associated with the method. The Binder.BindToMethod method of the Binder class is responsible for selecting the method to be invoked. The default binder selects the most specific match.

`InvokeMember` can be used to invoke methods with parameters that have default values. To bind to these methods, Reflection requires BindingFlags.OptionalParamBinding to be specified. For a parameter that has a default value, you can either supply a different value, or supply Missing.Value to use the default value.

For example, consider a method such as MyMethod(int x, float y = 2.0). To invoke this method with only the first argument as MyMethod(4), pass one of the above binding flags and pass two arguments, namely, 4 for the first argument and `Missing.Value` for the second argument. Unless you use `Missing.Value`, you may not omit optional parameters with the `Invoke` method. If you must do so, use `InvokeMember` instead.

Access restrictions are ignored for fully trusted code; that is, private constructors, methods, fields, and properties can be accessed and invoked through System.Reflection whenever the code is fully trusted.

You can use `Type.InvokeMember` to set a field to a particular value by specifying BindingFlags.SetField. For example, if you want to set a public instance field named F on class C, and F is a `String`, you can use code such as:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[]
{"strings new value"}, null, null, null);
```

If F is a `String[]`, you can use code such as:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[] {new
String[]{"a","z","c","d"}}, null, null, null);
```

which will initialize the field F to this new array. You can also use `Type.InvokeMember` to set a position in an array by supplying the index of the value and then the next value by using code such as the following:

```
typeof(C).InvokeMember("F", BindingFlags.SetField, null, c, new Object[] {1,
"b"}, null, null, null);
```

This will change string "z" in the array that F holds to string "b".

> **Note**
>
> Starting with the .NET Framework 2.0 Service Pack 1, this method can be used to access non-public members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the

grant set of the non-public members is restricted to the caller's grant set, or a subset thereof. (See **Security Considerations for Reflection**.)

To use this functionality, your application should target the .NET Framework 3.5 or later.

Type.IsArrayImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the IsArray property and determines whether the Type is an array.

C#

```
protected abstract bool IsArrayImpl ();
```

Returns

Boolean

`true` if the Type is an array; otherwise, `false`.

Examples

The following example overrides the `IsArrayImpl` method in the `MyTypeDelegator` class, checks if a variable is an array, and displays the result.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegator : TypeDelegator
{
    public string myElementType = null;
    public Type myType;
    public MyTypeDelegator(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override IsArrayImpl().
    protected override bool IsArrayImpl()
    {
        // Determine whether the type is an array.
        if(myType.IsArray)
        {
```

```
            myElementType = "array";
            return true;
        }
        // Return false if the type is not an array.
        return false;
    }
}
public class Type_IsArrayImpl
{
    public static void Main()
    {
        try
        {
            int myInt = 0 ;
            // Create an instance of an array element.
            int[] myArray = new int[5];
            MyTypeDelegator myType = new MyTypeDelegator(myArray.GetType());
            Console.WriteLine("\nDetermine whether the variable is an
array.\n");
            // Determine whether myType is an array type.
            if( myType.IsArray)
                Console.WriteLine("The type of myArray is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myArray is not an array.");
            myType = new MyTypeDelegator(myInt.GetType());

            // Determine whether myType is an array type.
            if( myType.IsArray)
                Console.WriteLine("The type of myInt is {0}.",
myType.myElementType);
            else
                Console.WriteLine("myInt is not an array.");
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message );
        }
    }
}
```

Remarks

An instance of the Array class must return `false` because it is an object, not an array.

Type.IsAssignableFrom(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether an instance of a specified type `c` can be assigned to a variable of the current type.

```
C#
public virtual bool IsAssignableFrom (Type? c);
```

Parameters

c Type

The type to compare with the current type.

Returns

Boolean

`true` if any of the following conditions is true:

- `c` and the current instance represent the same type.
- `c` is derived either directly or indirectly from the current instance. `c` is derived directly from the current instance if it inherits from the current instance; `c` is derived indirectly from the current instance if it inherits from a succession of one or more classes that inherit from the current instance.
- The current instance is an interface that `c` implements.
- `c` is a generic type parameter, and the current instance represents one of the constraints of `c`.
- `c` represents a value type, and the current instance represents `Nullable<c>` (`Nullable(Of c)` in Visual Basic).

`false` if none of these conditions are true, or if `c` is `null`.

Examples

The following example demonstrates the `IsAssignableFrom` method using defined classes, integer arrays, and generics.

C#

```
using System;
using System.Collections.Generic;
class Program
{
    public static void Main()
    {
            // Demonstrate classes:
            Console.WriteLine("Defined Classes:");
            Room room1 = new Room();
            Kitchen kitchen1 = new Kitchen();
            Bedroom bedroom1 = new Bedroom();
            Guestroom guestroom1 = new Guestroom();
            MasterBedroom masterbedroom1 = new MasterBedroom();

            Type room1Type = room1.GetType();
            Type kitchen1Type = kitchen1.GetType();
            Type bedroom1Type = bedroom1.GetType();
            Type guestroom1Type = guestroom1.GetType();
            Type masterbedroom1Type = masterbedroom1.GetType();

            Console.WriteLine("room assignable from kitchen: {0}",
room1Type.IsAssignableFrom(kitchen1Type));
            Console.WriteLine("bedroom assignable from guestroom: {0}",
bedroom1Type.IsAssignableFrom(guestroom1Type));
            Console.WriteLine("kitchen assignable from masterbedroom: {0}",
kitchen1Type.IsAssignableFrom(masterbedroom1Type));

            // Demonstrate arrays:
            Console.WriteLine();
            Console.WriteLine("Integer arrays:");

            int[] array2 = new int[2];
            int[] array10 = new int[10];
            int[,] array22 = new int[2, 2];
            int[,] array24 = new int[2, 4];

            Type array2Type = array2.GetType();
            Type array10Type = array10.GetType();
            Type array22Type = array22.GetType();
            Type array24Type = array24.GetType();

            Console.WriteLine("int[2] assignable from int[10]: {0}",
array2Type.IsAssignableFrom(array10Type));
```

```
            Console.WriteLine("int[2] assignable from int[2,4]: {0}",
array2Type.IsAssignableFrom(array24Type));
            Console.WriteLine("int[2,4] assignable from int[2,2]: {0}",
array24Type.IsAssignableFrom(array22Type));

            // Demonstrate generics:
            Console.WriteLine();
            Console.WriteLine("Generics:");

            // Note that "int?[]" is the same as "Nullable<int>[]"
            int?[] arrayNull = new int?[10];
            List<int> genIntList = new List<int>();
            List<Type> genTList = new List<Type>();

            Type arrayNullType = arrayNull.GetType();
            Type genIntListType = genIntList.GetType();
            Type genTListType = genTList.GetType();

            Console.WriteLine("int[10] assignable from int?[10]: {0}",
array10Type.IsAssignableFrom(arrayNullType));
            Console.WriteLine("List<int> assignable from List<Type>: {0}",
genIntListType.IsAssignableFrom(genTListType));
            Console.WriteLine("List<Type> assignable from List<int>: {0}",
genTListType.IsAssignableFrom(genIntListType));

            Console.ReadLine();
    }
}
class Room
{
}

class Kitchen : Room
{
}

class Bedroom : Room
{
}

class Guestroom : Bedroom
{
}

class MasterBedroom : Bedroom
{
}

//This code example produces the following output:
//
// Defined Classes:
// room assignable from kitchen: True
// bedroom assignable from guestroom: True
// kitchen assignable from masterbedroom: False
//
```

```
// Integer arrays:
// int[2] assignable from int[10]: True
// int[2] assignable from int[2,4]: False
// int[2,4] assignable from int[2,2]: True
//
// Generics:
// int[10] assignable from int?[10]: False
// List<int> assignable from List<Type>: False
// List<Type> assignable from List<int>: False
```

In the following example, the current instance is a Type object that represents the Stream class. `GenericWithConstraint` is a generic type whose generic type parameter must be of type Stream. Passing its generic type parameter to the `IsAssignableFrom` method indicates that an instance of the generic type parameter can be assigned to an Stream object.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      Type t = typeof(Stream);
      Type genericT = typeof(GenericWithConstraint<>);
      Type genericParam = genericT.GetGenericArguments()[0];
      Console.WriteLine(t.IsAssignableFrom(genericParam));
      // Displays True.
   }
}

public class GenericWithConstraint<T> where T : Stream
{}
```

Remarks

The IsAssignableFrom method can be used to determine whether an instance of `c` can be assigned to an instance of the current type, The method is most useful when you are handling objects whose types are not known at design time and allows for conditional assignment, as the following example shows.

C#

```
using System;
using System.Collections;
```

```
public class Example
{
   public static void Main()
   {
      Type t = typeof(IEnumerable);
      Type c = typeof(Array);

      IEnumerable instanceOfT;
      int[] instanceOfC = { 1, 2, 3, 4 };
      if (t.IsAssignableFrom(c))
         instanceOfT = instanceOfC;
  }
}
```

This method thus ensures that a line of code like the following will execute at runtime without throwing an InvalidCastException exception or a similar exception:

C#

```
instanceOfT = instanceOfC;
```

This method can be overridden by a derived class.

> **Note**
>
> A generic type definition is not assignable from a closed constructed type. That is, you cannot assign the closed constructed type `MyGenericList<int>` (`MyGenericList(Of Integer)` in Visual Basic) to a variable of type `MyGenericList<T>`.

If the `c` parameter is of type TypeBuilder, the result is based on the type that is to be built. The following code example demonstrates this using a built type named `B`.

C#

```
using System;
using System.Reflection;
using System.Reflection.Emit;

public class A
{}

public class Example
{
   public static void Main()
   {
      AppDomain domain = AppDomain.CurrentDomain;
```

```
        AssemblyName assemName = new AssemblyName();
        assemName.Name = "TempAssembly";

        // Define a dynamic assembly in the current application domain.
        AssemblyBuilder assemBuilder = domain.DefineDynamicAssembly(assemName,
                                                AssemblyBuilderAccess.Run);

        // Define a dynamic module in this assembly.
        ModuleBuilder moduleBuilder =
assemBuilder.DefineDynamicModule("TempModule");

        TypeBuilder b1 = moduleBuilder.DefineType("B", TypeAttributes.Public,
typeof(A));
        Console.WriteLine(typeof(A).IsAssignableFrom(b1));
    }
}
// The example displays the following output:
//         True
```

Type.IsAssignableTo(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the current type can be assigned to a variable of the specified `targetType`.

```
C#
public bool IsAssignableTo (Type? targetType);
```

Parameters

`targetType` Type

The type to compare with the current type.

Returns

Boolean

`true` if any of the following conditions is true:

- The current instance and `targetType` represent the same type.
- The current type is derived either directly or indirectly from `targetType`. The current type is derived directly from `targetType` if it inherits from `targetType`; the current type is derived indirectly from `targetType` if it inherits from a succession of one or more classes that inherit from `targetType`.
- `targetType` is an interface that the current type implements.
- The current type is a generic type parameter, and `targetType` represents one of the constraints of the current type.
- The current type represents a value type, and `targetType` represents `Nullable<c>` (`Nullable(Of c)` in Visual Basic).

`false` if none of these conditions are true, or if `targetType` is `null`.

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

Type.IsByRefImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the IsByRef property and determines whether the Type is passed by reference.

C#

```
protected abstract bool IsByRefImpl ();
```

Returns

Boolean

`true` if the Type is passed by reference; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsCOMObjectImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the IsCOMObject property and determines whether the Type is a COM object.

```
C#
protected abstract bool IsCOMObjectImpl ();
```

Returns

Boolean

`true` if the Type is a COM object; otherwise, `false`.

Remarks

This method returns `false` for COM interfaces because they are not objects. COM interfaces can be implemented by Microsoft .NET Framework objects.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsContextfulImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Implements the IsContextful property and determines whether the Type can be hosted in a context.

C#

```
protected virtual bool IsContextfulImpl ();
```

Returns

Boolean

`true` if the Type can be hosted in a context; otherwise, `false`.

Examples

The following example demonstrates a use of the `IsContextfulImpl` method.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegatorClass : TypeDelegator
{
    public string myElementType = null;
    private Type myType = null ;

    public MyTypeDelegatorClass(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override IsContextfulImpl.
    protected override bool IsContextfulImpl()
    {
        // Check whether the type is contextful.
        if(myType.IsContextful)
        {
```

```
            myElementType = " is contextful ";
            return true;
        }
        return false;
    }
}
public class MyTypeDemoClass
{
    public static void Main()
    {
        try
        {
            MyTypeDelegatorClass myType;
            Console.WriteLine ("Check whether MyContextBoundClass can be
hosted in a context.");
            // Check whether MyContextBoundClass is contextful.
            myType = new MyTypeDelegatorClass(typeof(MyContextBoundClass));
            if( myType.IsContextful)
            {
                Console.WriteLine(typeof(MyContextBoundClass) + " can be
hosted in a context.");
            }
            else
            {
                Console.WriteLine(typeof(MyContextBoundClass) + " cannot be
hosted in a context.");
            }
            // Check whether the int type is contextful.
            myType = new MyTypeDelegatorClass(typeof(MyTypeDemoClass));
            Console.WriteLine ("\nCheck whether MyTypeDemoClass can be
hosted in a context.");
            if( myType.IsContextful)
            {
                Console.WriteLine(typeof(MyTypeDemoClass) + " can be hosted
in a context.");
            }
            else
            {
                Console.WriteLine(typeof(MyTypeDemoClass) + " cannot be
hosted in a context.");
            }
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message);
        }
    }
}
// This class demonstrates IsContextfulImpl.
public class MyContextBoundClass : ContextBoundObject
{
    public string myString = "This class is used to demonstrate members of
the Type class.";
}
```

Remarks

This method can be overridden by a derived class.

A context intercepts calls to the class members and enforce policies that are applied to the class, such as synchronization.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsEnumDefined(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the specified value exists in the current enumeration type.

```
C#
public virtual bool IsEnumDefined (object value);
```

Parameters

`value` Object

The value to be tested.

Returns

Boolean

`true` if the specified value is a member of the current enumeration type; otherwise, `false`.

Exceptions

ArgumentException

The current type is not an enumeration.

ArgumentNullException

`value` is `null`.

InvalidOperationException

`value` is of a type that cannot be the underlying type of an enumeration.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsEquivalentTo(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two COM types have the same identity and are eligible for type equivalence.

```
C#
public virtual bool IsEquivalentTo (Type? other);
```

Parameters

`other` Type

The COM type that is tested for equivalence with the current type.

Returns

Boolean

`true` if the COM types are equivalent; otherwise, `false`. This method also returns `false` if one type is in an assembly that is loaded for execution, and the other is in an assembly that is loaded into the reflection-only context.

Remarks

Beginning with the .NET Framework 4, the common language runtime supports the embedding of type information for COM types directly into managed assemblies, instead of requiring the managed assemblies to obtain type information for COM types from interop assemblies. Because the embedded type information includes only the types and members that are actually used by a managed assembly, two managed assemblies might have very different views of the same COM type. Each managed assembly has a different Type object to represent its view of the COM type. The common language runtime supports type equivalence between these different views for interfaces, structures, enumerations, and delegates.

Type equivalence means that a COM object that is passed from one managed assembly to another can be cast to the appropriate managed type in the receiving assembly. The IsEquivalentTo method enables an assembly to determine that a COM object obtained from another assembly has the same COM identity as one of the first assembly's own embedded interop types, and thus can be cast to that type.

For more information, see Type Equivalence and Embedded Interop Types.

Type.IsInstanceOfType(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified object is an instance of the current Type.

C#

```
public virtual bool IsInstanceOfType (object? o);
```

Parameters

o Object

The object to compare with the current type.

Returns

Boolean

`true` if the current `Type` is in the inheritance hierarchy of the object represented by `o`, or if the current `Type` is an interface that `o` implements. `false` if neither of these conditions is the case, if `o` is `null`, or if the current `Type` is an open generic type (that is, ContainsGenericParameters returns `true`).

Examples

The following example demonstrates the use of the `IsInstanceOfType` method.

C#

```
using System;

public interface IExample {}

public class BaseClass : IExample {}

public class DerivedClass : BaseClass {}
```

```
public class Example
{
    public static void Main()
    {
        var interfaceType = typeof(IExample);
        var base1 = new BaseClass();
        var base1Type = base1.GetType();
        var derived1 = new DerivedClass();
        var derived1Type = derived1.GetType();
        int[] arr = new int[11];

        Console.WriteLine("Is int[] an instance of the Array class? {0}.",
                           typeof(Array).IsInstanceOfType(arr));
        Console.WriteLine("Is base1 an instance of BaseClass? {0}.",
                          base1Type.IsInstanceOfType(base1));
        Console.WriteLine("Is derived1 an instance of BaseClass? {0}.",
                          base1Type.IsInstanceOfType(derived1));
        Console.WriteLine("Is base1 an instance of IExample? {0}.",
                          interfaceType.IsInstanceOfType(base1));
        Console.WriteLine("Is derived1 an instance of IExample? {0}.",
                          interfaceType.IsInstanceOfType(derived1));
    }
}
// The example displays the following output:
//    Is int[] an instance of the Array class? True.
//    Is base1 an instance of BaseClass? True.
//    Is derived1 an instance of BaseClass? True.
//    Is base1 an instance of IExample? True.
//    Is derived1 an instance of IExample? True.
```

Remarks

This method can be overridden by a derived class.

> ⓘ **Note**
>
> A constructed type is not an instance of its generic type definition. That is, `MyGenericList<int>` (`MyGenericList(Of Integer)` in Visual Basic) is not an instance of `MyGenericList<T>` (`MyGenericList(Of T)` in Visual Basic).

Type.IsMarshalByRefImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Implements the IsMarshalByRef property and determines whether the Type is marshaled by reference.

C#

```
protected virtual bool IsMarshalByRefImpl ();
```

Returns

Boolean

`true` if the Type is marshaled by reference; otherwise, `false`.

Examples

The following example determines whether the given type is marshaled by reference and displays the result.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegatorClass : TypeDelegator
{
    public string myElementType = null;
    private Type myType = null ;
    public MyTypeDelegatorClass(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override IsMarshalByRefImpl.
    protected override bool IsMarshalByRefImpl()
    {
        // Determine whether the type is marshalled by reference.
        if(myType.IsMarshalByRef)
        {
```

```
            myElementType = " marshalled by reference";
            return true;
        }
        return false;
    }
}
public class MyTypeDemoClass
{
    public static void Main()
    {
        try
        {
            MyTypeDelegatorClass myType;
            Console.WriteLine ("Determine whether MyContextBoundClass is
marshalled by reference.");
            // Determine whether MyContextBoundClass type is marshalled by
reference.
            myType = new MyTypeDelegatorClass(typeof(MyContextBoundClass));
            if( myType.IsMarshalByRef )
            {
                Console.WriteLine(typeof(MyContextBoundClass) + " is
marshalled by reference.");
            }
            else
            {
                Console.WriteLine(typeof(MyContextBoundClass) + " is not
marshalled by reference.");
            }

            // Determine whether int type is marshalled by reference.
            myType = new MyTypeDelegatorClass(typeof(int));
            Console.WriteLine ("\nDetermine whether int is marshalled by
reference.");
            if( myType.IsMarshalByRef)
            {
                Console.WriteLine(typeof(int) + " is marshalled by
reference.");
            }
            else
            {
                Console.WriteLine(typeof(int) + " is not marshalled by
reference.");
            }
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message);
        }
    }
}
// This class is used to demonstrate the IsMarshalByRefImpl method.
public class MyContextBoundClass : ContextBoundObject
{
    public string myString = "This class is used to demonstrate members of
```

```
the Type class.";
}
```

Remarks

This method can be overridden by a derived class.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsPointerImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the IsPointer property and determines whether the Type is a pointer.

```
C#
protected abstract bool IsPointerImpl ();
```

Returns

Boolean

`true` if the Type is a pointer; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsPrimitiveImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

When overridden in a derived class, implements the IsPrimitive property and determines whether the Type is one of the primitive types.

C#

```
protected abstract bool IsPrimitiveImpl ();
```

Returns

Boolean

`true` if the Type is one of the primitive types; otherwise, `false`.

Examples

The following example determines whether the given type is a primitive type and displays the result.

C#

```
using System;
using System.Reflection;
public class MyTypeDelegatorClass : TypeDelegator
{
    public string myElementType = null;
    private Type myType = null ;
    public MyTypeDelegatorClass(Type myType) : base(myType)
    {
        this.myType = myType;
    }
    // Override the IsPrimitiveImpl.
    protected override bool IsPrimitiveImpl()
    {
        // Determine whether the type is a primitive type.
        if(myType.IsPrimitive)
        {
```

```
            myElementType = "primitive";
            return true;
        }
        return false;
    }
}
public class MyTypeDemoClass
{
    public static void Main()
    {
        try
        {
            Console.WriteLine ("Determine whether int is a primitive
type.");
            MyTypeDelegatorClass myType;
            myType = new MyTypeDelegatorClass(typeof(int));
            // Determine whether int is a primitive type.
            if( myType.IsPrimitive)
            {
                Console.WriteLine(typeof(int) + " is a primitive type.");
            }
            else
            {
                Console.WriteLine(typeof(int) + " is not a primitive
type.");
            }
            Console.WriteLine ("\nDetermine whether string is a primitive
type.");
            myType = new MyTypeDelegatorClass(typeof(string));
            // Determine if string is a primitive type.
            if( myType.IsPrimitive)
            {
                Console.WriteLine(typeof(string) + " is a primitive type.");
            }
            else
            {
                Console.WriteLine(typeof(string) + " is not a primitive
type.");
            }
        }
        catch( Exception e )
        {
            Console.WriteLine("Exception: {0}", e.Message);
        }
    }
}
```

Remarks

The primitive types are Boolean, Byte, SByte, Int16, UInt16, Int32, UInt32, Int64, UInt64, Char, Double, and Single.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.IsSubclassOf(Type) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the current Type derives from the specified Type.

```
C#
public virtual bool IsSubclassOf (Type c);
```

Parameters

c Type

The type to compare with the current type.

Returns

Boolean

`true` if the current `Type` derives from `c`; otherwise, `false`. This method also returns `false` if `c` and the current `Type` are equal.

Exceptions

ArgumentNullException

`c` is `null`.

Examples

The following example creates a class named `Class1` and a derived class named `DerivedC1`. It calls the IsSubclassOf method to show that `DerivedC1` is a subclass of `Class1`.

```
C#
```

```
using System;

public class Class1 { }
public class DerivedC1 : Class1 { }

class IsSubclassTest
{
   public static void Main()
   {
      Console.WriteLine("DerivedC1 subclass of Class1: {0}",
                        typeof(DerivedC1).IsSubclassOf(typeof(Class1)));
   }
}
// The example displays the following output:
//        DerivedC1 subclass of Class1: True
```

Remarks

You can call the IsSubclassOf method to determine any of the following:

- Whether one class derives from another.
- Whether a type derives from ValueType. However, the IsValueType is a more efficient way to determine whether a type is a value type.
- Whether a type derives from Enum. However, the IsEnum method is a more efficient way to determine whether a type is an enumeration.
- Whether a type is a delegate, that is, whether it derives from either Delegate or MulticastDelegate.

The IsSubclassOf method cannot be used to determine whether an interface derives from another interface, or whether a class implements an interface. Use the IsAssignableFrom method for that purpose, as the following example shows.

C#

```
using System;

public interface IInterface
{
   void Display();
}

public class Implementation : IInterface
{
   public void Display()
   {
```

```
        Console.WriteLine("The implementation...");
    }
}

public class Example
{
    public static void Main()
    {
        Console.WriteLine("Implementation is a subclass of IInterface:   {0}",

typeof(Implementation).IsSubclassOf(typeof(IInterface)));
        Console.WriteLine("IInterface is assignable from Implementation: {0}",

typeof(IInterface).IsAssignableFrom(typeof(Implementation)));
    }
}
// The example displays the following output:
//       Implementation is a subclass of IInterface:   False
//       IInterface is assignable from Implementation: True
```

If the current Type represents a type parameter in the definition of a generic type or generic method, it derives from its class constraint or from System.Object if it has no class constraint.

> **Note**
>
> Except when used with interfaces, **IsSubclassOf** is the converse of **IsAssignableFrom**. That is, if `t1.IsSubclassOf(t2)` is `true`, then `t2.IsAssignableFrom(t1)` is also `true`.

This method can be overridden by a derived class.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.IsValueTypeImpl Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Implements the IsValueType property and determines whether the Type is a value type; that is, not a class or an interface.

```
C#
protected virtual bool IsValueTypeImpl ();
```

Returns

Boolean

`true` if the Type is a value type; otherwise, `false`.

Remarks

This method is provided to enable the implementation of alternate type systems. It is not generally used in application code.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Type.MakeArrayType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a Type object that represents an array of the current type.

Overloads

Expand table

MakeArrayType()	Returns a Type object representing a one-dimensional array of the current type, with a lower bound of zero.
MakeArrayType(Int32)	Returns a Type object representing an array of the current type, with the specified number of dimensions.

Examples

The following code example creates array, `ref` (`ByRef` in Visual Basic), and pointer types for the `Test` class.

C#

```
using System;
using System.Reflection;

public class Example
{
    public static void Main()
    {
        // Create a Type object that represents a one-dimensional
        // array of Example objects.
        Type t = typeof(Example).MakeArrayType();
        Console.WriteLine("\r\nArray of Example: {0}", t);

        // Create a Type object that represents a two-dimensional
        // array of Example objects.
        t = typeof(Example).MakeArrayType(2);
        Console.WriteLine("\r\nTwo-dimensional array of Example: {0}", t);
```

```
        // Demonstrate an exception when an invalid array rank is
        // specified.
        try
        {
            t = typeof(Example).MakeArrayType(-1);
        }
        catch(Exception ex)
        {
            Console.WriteLine("\r\n{0}", ex);
        }

        // Create a Type object that represents a ByRef parameter
        // of type Example.
        t = typeof(Example).MakeByRefType();
        Console.WriteLine("\r\nByRef Example: {0}", t);

        // Get a Type object representing the Example class, a
        // MethodInfo representing the "Test" method, a ParameterInfo
        // representing the parameter of type Example, and finally
        // a Type object representing the type of this ByRef parameter.
        // Compare this Type object with the Type object created using
        // MakeByRefType.
        Type t2 = typeof(Example);
        MethodInfo mi = t2.GetMethod("Test");
        ParameterInfo pi = mi.GetParameters()[0];
        Type pt = pi.ParameterType;
        Console.WriteLine("Are the ByRef types equal? {0}", (t == pt));

        // Create a Type object that represents a pointer to an
        // Example object.
        t = typeof(Example).MakePointerType();
        Console.WriteLine("\r\nPointer to Example: {0}", t);
    }

    // A sample method with a ByRef parameter.
    //
    public void Test(ref Example e)
    {
    }
}

/* This example produces output similar to the following:

Array of Example: Example[]

Two-dimensional array of Example: Example[,]

System.IndexOutOfRangeException: Index was outside the bounds of the array.
   at System.RuntimeType.MakeArrayType(Int32 rank) in
c:\vbl\ndp\clr\src\BCL\System\RtType.cs:line 2999
   at Example.Main()

ByRef Example: Example&
Are the ByRef types equal? True
```

```
Pointer to Example: Example*

 */
```

MakeArrayType()

Returns a Type object representing a one-dimensional array of the current type, with a lower bound of zero.

```
C#

public virtual Type MakeArrayType ();
```

Returns

Type

A Type object representing a one-dimensional array of the current type, with a lower bound of zero.

Exceptions

NotSupportedException

The invoked method is not supported in the base class. Derived classes must provide an implementation.

TypeLoadException

The current type is TypedReference.

-or-

The current type is a `ByRef` type. That is, IsByRef returns `true`.

Remarks

The MakeArrayType method provides a way to generate array types whose element types are computed at run time.

Note The common language runtime makes a distinction between vectors (that is, one-dimensional arrays that are always zero-based) and multidimensional arrays. A vector, which always has only one dimension, is not the same as a multidimensional array that happens to have only one dimension. This method overload can only be

used to create vector types, and it is the only way to create a vector type. Use the MakeArrayType(Int32) method overload to create multidimensional array types.

- MakeByRefType()
- MakePointerType()

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

MakeArrayType(Int32)

Returns a Type object representing an array of the current type, with the specified number of dimensions.

C#

```
public virtual Type MakeArrayType (int rank);
```

Parameters

`rank` Int32

The number of dimensions for the array. This number must be less than or equal to 32.

Returns

Type

An object representing an array of the current type, with the specified number of dimensions.

Exceptions

IndexOutOfRangeException

`rank` is invalid. For example, 0 or negative.

NotSupportedException

The invoked method is not supported in the base class.

TypeLoadException

The current type is TypedReference.

-or-

The current type is a `ByRef` type. That is, IsByRef returns `true`.

-or-

`rank` is greater than 32.

Remarks

The MakeArrayType method provides a way to generate array types whose element types are computed at run time.

> **Note**
>
> The common language runtime makes a distinction between vectors (that is, one-dimensional arrays that are always zero-based) and multidimensional arrays. A vector, which always has only one dimension, is not the same as a multidimensional array that happens to have only one dimension. You cannot use this method overload to create a vector type; if `rank` is 1, this method overload returns a multidimensional array type that happens to have one dimension. Use the **MakeArrayType()** method overload to create vector types.

Type.MakeByRefType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a Type object that represents the current type when passed as a `ref` parameter (`ByRef` parameter in Visual Basic).

C#

```
public virtual Type MakeByRefType ();
```

Returns

Type

A Type object that represents the current type when passed as a `ref` parameter (`ByRef` parameter in Visual Basic).

Exceptions

NotSupportedException

The invoked method is not supported in the base class.

TypeLoadException

The current type is TypedReference.

-or-

The current type is a `ByRef` type. That is, IsByRef returns `true`.

Examples

The following code example creates array, `ref` (`ByRef` in Visual Basic), and pointer types for the `Test` class.

C#

```
using System;
using System.Reflection;

public class Example
{
    public static void Main()
    {
        // Create a Type object that represents a one-dimensional
        // array of Example objects.
        Type t = typeof(Example).MakeArrayType();
        Console.WriteLine("\r\nArray of Example: {0}", t);

        // Create a Type object that represents a two-dimensional
        // array of Example objects.
        t = typeof(Example).MakeArrayType(2);
        Console.WriteLine("\r\nTwo-dimensional array of Example: {0}", t);

        // Demonstrate an exception when an invalid array rank is
        // specified.
        try
        {
            t = typeof(Example).MakeArrayType(-1);
        }
        catch(Exception ex)
        {
            Console.WriteLine("\r\n{0}", ex);
        }

        // Create a Type object that represents a ByRef parameter
        // of type Example.
        t = typeof(Example).MakeByRefType();
        Console.WriteLine("\r\nByRef Example: {0}", t);

        // Get a Type object representing the Example class, a
        // MethodInfo representing the "Test" method, a ParameterInfo
        // representing the parameter of type Example, and finally
        // a Type object representing the type of this ByRef parameter.
        // Compare this Type object with the Type object created using
        // MakeByRefType.
        Type t2 = typeof(Example);
        MethodInfo mi = t2.GetMethod("Test");
        ParameterInfo pi = mi.GetParameters()[0];
        Type pt = pi.ParameterType;
        Console.WriteLine("Are the ByRef types equal? {0}", (t == pt));

        // Create a Type object that represents a pointer to an
        // Example object.
        t = typeof(Example).MakePointerType();
        Console.WriteLine("\r\nPointer to Example: {0}", t);
    }

    // A sample method with a ByRef parameter.
    //
    public void Test(ref Example e)
```

```
    {
    }
}

/* This example produces output similar to the following:

Array of Example: Example[]

Two-dimensional array of Example: Example[,]

System.IndexOutOfRangeException: Index was outside the bounds of the array.
   at System.RuntimeType.MakeArrayType(Int32 rank) in
c:\vbl\ndp\clr\src\BCL\System\RtType.cs:line 2999
   at Example.Main()

ByRef Example: Example&
Are the ByRef types equal? True

Pointer to Example: Example*

 */
```

Remarks

The MakeByRefType method provides a way to generate `ref` types (`ByRef` in Visual Basic) for parameter lists.

Using the syntax of Microsoft intermediate language (MSIL), if the current Type object represents Int32, this method returns a Type object representing `Int32&`.

Applies to

Product	Versions

Type.MakeGenericMethodParameter(Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a signature type object that can be passed into the `Type[]` array parameter of a GetMethod method to represent a generic parameter reference.

```
C#
public static Type MakeGenericMethodParameter (int position);
```

Parameters

`position` Int32

The typed parameter position.

Returns

Type

A signature type object that can be passed into the `Type[]` array parameter of a GetMethod method to represent a generic parameter reference.

Exceptions

ArgumentOutOfRangeException

`position` is negative.

Applies to

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Collaborate with us on GitHub

Type.MakeGenericSignatureType(Type, Type[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a generic signature type, which allows third party reimplementations of Reflection to fully support the use of signature types in querying type members.

C#

```
public static Type MakeGenericSignatureType (Type genericTypeDefinition,
params Type[] typeArguments);
```

Parameters

`genericTypeDefinition` Type

The generic type definition.

`typeArguments` Type[]

An array of type arguments.

Returns

Type

A generic signature type.

Applies to

Product	Versions
.NET	Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.MakeGenericType(Type[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Substitutes the elements of an array of types for the type parameters of the current generic type definition and returns a Type object representing the resulting constructed type.

```
C#
public virtual Type MakeGenericType (params Type[] typeArguments);
```

Parameters

typeArguments Type[]

An array of types to be substituted for the type parameters of the current generic type.

Returns

Type

A Type representing the constructed type formed by substituting the elements of `typeArguments` for the type parameters of the current generic type.

Exceptions

InvalidOperationException

The current type does not represent a generic type definition. That is, IsGenericTypeDefinition returns `false`.

ArgumentNullException

`typeArguments` is `null`.

-or-

Any element of `typeArguments` is `null`.

ArgumentException

The number of elements in `typeArguments` is not the same as the number of type parameters in the current generic type definition.

-or-

Any element of `typeArguments` does not satisfy the constraints specified for the corresponding type parameter of the current generic type.

-or-

`typeArguments` contains an element that is a pointer type (IsPointer returns `true`), a by-ref type (IsByRef returns `true`), or Void.

NotSupportedException

The invoked method is not supported in the base class. Derived classes must provide an implementation.

Examples

The following example uses the MakeGenericType method to create a constructed type from the generic type definition for the Dictionary<TKey,TValue> type. The constructed type represents a Dictionary<TKey,TValue> of `Test` objects with string keys.

C#

```
using System;
using System.Reflection;
using System.Collections.Generic;

public class Test
{
    public static void Main()
    {
        Console.WriteLine("\r\n--- Create a constructed type from the
generic Dictionary type.");

        // Create a type object representing the generic Dictionary
        // type, by omitting the type arguments (but keeping the
        // comma that separates them, so the compiler can infer the
        // number of type parameters).
        Type generic = typeof(Dictionary<,>);
        DisplayTypeInfo(generic);

        // Create an array of types to substitute for the type
        // parameters of Dictionary. The key is of type string, and
        // the type to be contained in the Dictionary is Test.
```

```
        Type[] typeArgs = { typeof(string), typeof(Test) };

        // Create a Type object representing the constructed generic
        // type.
        Type constructed = generic.MakeGenericType(typeArgs);
        DisplayTypeInfo(constructed);

        // Compare the type objects obtained above to type objects
        // obtained using typeof() and GetGenericTypeDefinition().
        Console.WriteLine("\r\n--- Compare types obtained by different
methods:");

        Type t = typeof(Dictionary<String, Test>);
        Console.WriteLine("\tAre the constructed types equal? {0}", t ==
constructed);
        Console.WriteLine("\tAre the generic types equal? {0}",
            t.GetGenericTypeDefinition() == generic);
    }

    private static void DisplayTypeInfo(Type t)
    {
        Console.WriteLine("\r\n{0}", t);

        Console.WriteLine("\tIs this a generic type definition? {0}",
            t.IsGenericTypeDefinition);

        Console.WriteLine("\tIs it a generic type? {0}",
            t.IsGenericType);

        Type[] typeArguments = t.GetGenericArguments();
        Console.WriteLine("\tList type arguments ({0}):",
typeArguments.Length);
        foreach (Type tParam in typeArguments)
        {
            Console.WriteLine("\t\t{0}", tParam);
        }
    }
}

/* This example produces the following output:

--- Create a constructed type from the generic Dictionary type.

System.Collections.Generic.Dictionary`2[TKey,TValue]
        Is this a generic type definition? True
        Is it a generic type? True
        List type arguments (2):
                TKey
                TValue

System.Collections.Generic.Dictionary`2[System.String, Test]
        Is this a generic type definition? False
        Is it a generic type? True
        List type arguments (2):
                System.String
```

```
                 Test

--- Compare types obtained by different methods:
        Are the constructed types equal? True
        Are the generic types equal? True
 */
```

Remarks

For more information about this API, see Supplemental API remarks for Type.MakeGenericType.

Applies to

Type.MakePointerType Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a Type object that represents a pointer to the current type.

```
C#

public virtual Type MakePointerType ();
```

Returns

Type

A Type object that represents a pointer to the current type.

Exceptions

NotSupportedException

The invoked method is not supported in the base class.

TypeLoadException

The current type is TypedReference.

-or-

The current type is a `ByRef` type. That is, IsByRef returns `true`.

Examples

The following code example creates array, `ref` (`ByRef` in Visual Basic), and pointer types for the `Test` class.

```
C#

using System;
using System.Reflection;
```

```
public class Example
{
    public static void Main()
    {
        // Create a Type object that represents a one-dimensional
        // array of Example objects.
        Type t = typeof(Example).MakeArrayType();
        Console.WriteLine("\r\nArray of Example: {0}", t);

        // Create a Type object that represents a two-dimensional
        // array of Example objects.
        t = typeof(Example).MakeArrayType(2);
        Console.WriteLine("\r\nTwo-dimensional array of Example: {0}", t);

        // Demonstrate an exception when an invalid array rank is
        // specified.
        try
        {
            t = typeof(Example).MakeArrayType(-1);
        }
        catch(Exception ex)
        {
            Console.WriteLine("\r\n{0}", ex);
        }

        // Create a Type object that represents a ByRef parameter
        // of type Example.
        t = typeof(Example).MakeByRefType();
        Console.WriteLine("\r\nByRef Example: {0}", t);

        // Get a Type object representing the Example class, a
        // MethodInfo representing the "Test" method, a ParameterInfo
        // representing the parameter of type Example, and finally
        // a Type object representing the type of this ByRef parameter.
        // Compare this Type object with the Type object created using
        // MakeByRefType.
        Type t2 = typeof(Example);
        MethodInfo mi = t2.GetMethod("Test");
        ParameterInfo pi = mi.GetParameters()[0];
        Type pt = pi.ParameterType;
        Console.WriteLine("Are the ByRef types equal? {0}", (t == pt));

        // Create a Type object that represents a pointer to an
        // Example object.
        t = typeof(Example).MakePointerType();
        Console.WriteLine("\r\nPointer to Example: {0}", t);
    }

    // A sample method with a ByRef parameter.
    //
    public void Test(ref Example e)
    {
    }
}
```

```
/* This example produces output similar to the following:

Array of Example: Example[]

Two-dimensional array of Example: Example[,]

System.IndexOutOfRangeException: Index was outside the bounds of the array.
   at System.RuntimeType.MakeArrayType(Int32 rank) in
c:\vbl\ndp\clr\src\BCL\System\RtType.cs:line 2999
   at Example.Main()

ByRef Example: Example&
Are the ByRef types equal? True

Pointer to Example: Example*

 */
```

Remarks

The MakePointerType method provides a way to generate pointer types for parameter lists.

Using the syntax of Microsoft intermediate language (MSIL), if the current Type object represents Int32, this method returns a Type object representing `Int32*`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.ReflectionOnlyGetType(String, Boolean, Boolean) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> ReflectionOnly loading is not supported and throws PlatformNotSupportedException.

Gets the Type with the specified name, specifying whether to perform a case-sensitive search and whether to throw an exception if the type is not found. The type is loaded for reflection only, not for execution.

C#

```
[System.Obsolete("ReflectionOnly loading is not supported and throws PlatformNotSupportedException.", DiagnosticId="SYSLIB0018", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public static Type? ReflectionOnlyGetType (string typeName, bool throwIfNotFound, bool ignoreCase);
```

Parameters

`typeName` String

The assembly-qualified name of the Type to get.

`throwIfNotFound` Boolean

`true` to throw a TypeLoadException if the type cannot be found; `false` to return `null` if the type cannot be found. Specifying `false` also suppresses some other exception conditions, but not all of them. See the Exceptions section.

`ignoreCase` Boolean

`true` to perform a case-insensitive search for `typeName`; `false` to perform a case-sensitive search for `typeName`.

Returns

Type

The type with the specified name, if found; otherwise, `null`. If the type is not found, the `throwIfNotFound` parameter specifies whether `null` is returned or an exception is thrown. In some cases, an exception is thrown regardless of the value of `throwIfNotFound`. See the Exceptions section.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`typeName` is `null`.

TargetInvocationException

A class initializer is invoked and throws an exception.

TypeLoadException

`throwIfNotFound` is `true` and the type is not found.

-or-

`throwIfNotFound` is `true` and `typeName` contains invalid characters, such as an embedded tab.

-or-

`throwIfNotFound` is `true` and `typeName` is an empty string.

-or-

`throwIfNotFound` is `true` and `typeName` represents an array type with an invalid size.

-or-

`typeName` represents an array of TypedReference objects.

ArgumentException

`typeName` does not include the assembly name.

-or-

`throwIfNotFound` is `true` and `typeName` contains invalid syntax; for example, "MyType[,*,]".

-or-

`typeName` represents a generic type that has a pointer type, a `ByRef` type, or Void as one of its type arguments.

-or-

`typeName` represents a generic type that has an incorrect number of type arguments.

-or-

`typeName` represents a generic type, and one of its type arguments does not satisfy the constraints for the corresponding type parameter.

FileNotFoundException
`throwIfNotFound` is `true` and the assembly or one of its dependencies was not found.

FileLoadException
The assembly or one of its dependencies was found, but could not be loaded.

BadImageFormatException
The assembly or one of its dependencies is not valid.

-or-

The assembly was compiled with a later version of the common language runtime than the version that is currently loaded.

PlatformNotSupportedException
.NET Core and .NET 5+ only: In all cases.

Remarks

If the assembly containing the type is not already loaded into the reflection-only context, using the ReflectionOnlyGetType method is equivalent to first loading the assembly for reflection only, using the ReflectionOnlyLoad method, and then loading

the type by calling the assembly's Assembly.GetType method. For information about assembly-qualified names, see the Type.AssemblyQualifiedName property. For additional details on specifying type names, see the GetType(String, Boolean, Boolean) method overload.

If the assembly is already loaded for execution, another copy is loaded into the reflection-only context.

The `throwIfNotFound` parameter specifies what happens when the type is not found, and also suppresses certain other exception conditions, as described in the Exceptions section. Some exceptions are thrown regardless of the value of `throwIfNotFound`. For example, if the assembly is not valid, a BadImageFormatException is thrown even if `throwIfNotFound` is `false`.

For more information about using the reflection-only context, see How to: Load Assemblies into the Reflection-Only Context.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5 *(6, 7, 8, 9)*
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a `String` representing the name of the current `Type`.

C#

```
public override string ToString ();
```

Returns

String

A String representing the name of the current Type.

Examples

This following example demonstrates a use of the Namespace and Module properties and the `ToString` method of Type.

C#

```
using System;

namespace MyNamespace
{
    class MyClass
    {
    }
}

public class Example
{
    public static void Main()
    {
         Type myType = typeof(MyNamespace.MyClass);
         Console.WriteLine("Displaying information about {0}:", myType);
         // Get the namespace of the myClass class.
         Console.WriteLine("   Namespace: {0}.", myType.Namespace);
```

```
        // Get the name of the module.
        Console.WriteLine("   Module: {0}.", myType.Module);
        // Get the fully qualified type name.
        Console.WriteLine("   Fully qualified name: {0}.",
myType.ToString());
    }
}
// The example displays the following output:
//    Displaying information about MyNamespace.MyClass:
//       Namespace: MyNamespace.
//       Module: type_tostring.exe.
//       Fully qualified name: MyNamespace.MyClass.
```

The following example compares the strings returned by the `ToString` method and the Name, FullName, and AssemblyQualifiedName properties.

C#

```
using System;
using System.Collections.Generic;
using System.Globalization;

public class Example
{
    public static void Main()
    {
        Type t = typeof(String);
        ShowTypeInfo(t);

        t = typeof(List<>);
        ShowTypeInfo(t);

        var list = new List<String>();
        t = list.GetType();
        ShowTypeInfo(t);

        Object v = 12;
        t = v.GetType();
        ShowTypeInfo(t);

        t = typeof(IFormatProvider);
        ShowTypeInfo(t);

        IFormatProvider ifmt = NumberFormatInfo.CurrentInfo;
        t = ifmt.GetType();
        ShowTypeInfo(t);
    }

    private static void ShowTypeInfo(Type t)
    {
        Console.WriteLine($"Name: {t.Name}");
        Console.WriteLine($"Full Name: {t.FullName}");
        Console.WriteLine($"ToString:  {t}");
```

```
        Console.WriteLine($"Assembly Qualified Name:
{t.AssemblyQualifiedName}");
        Console.WriteLine();
    }
}
// The example displays output like the following:
//    Name: String
//    Full Name: System.String
//    ToString:  System.String
//    Assembly Qualified Name: System.String, mscorlib, Version=4.0.0.0,
Culture=neutr
//    al, PublicKeyToken=b77a5c561934e089
//
//    Name: List`1
//    Full Name: System.Collections.Generic.List`1
//    ToString:  System.Collections.Generic.List`1[T]
//    Assembly Qualified Name: System.Collections.Generic.List`1, mscorlib,
Version=4.
//    0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089

//    ure=neutral, PublicKeyToken=b77a5c561934e089
//
//    Name: NumberFormatInfo
//    Full Name: System.Globalization.NumberFormatInfo
//    ToString:  System.Globalization.NumberFormatInfo
//    Assembly Qualified Name: System.Globalization.NumberFormatInfo,
mscorlib, Versio
//    n=4.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089
```

Remarks

This method returns the fully qualified common language runtime namespace and name for all primitive types. For example, the C# instruction, `(long)0.Type().ToString()` returns "System.Int64" instead of merely "Int64".

If the current Type represents a generic type, the type and its type arguments are qualified by namespace and by nested type, but not by assembly. If the current Type represents a type parameter in the definition of a generic type or generic method, this method returns the unqualified name of the type parameter.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Type.Equality(Type, Type) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two Type objects are equal.

C#

```
public static bool operator == (Type? left, Type? right);
```

Parameters

`left` Type

The first object to compare.

`right` Type

The second object to compare.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Type.Inequality(Type, Type) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether two Type objects are not equal.

C#

```
public static bool operator != (Type? left, Type? right);
```

Parameters

`left` Type

The first object to compare.

`right` Type

The second object to compare.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypeAccessException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when a method attempts to use a type that it does not have access to.

```
C#
public class TypeAccessException : TypeLoadException
```

Inheritance Object → Exception → SystemException → TypeLoadException → TypeAccessException

Remarks

TypeAccessException is thrown when a method attempts to cast an object to a type that is not accessible from the method. For example, an anonymously hosted dynamic method cannot access a security-critical type because the method is transparent. If the method contains a OpCodes.Castclass instruction that casts an object to a security-critical type, or to a generic type that has a security-critical type as one of its type parameters, TypeAccessException is thrown by the JIT compiler.

Similarly, TypeAccessException is thrown for a dynamic method that uses an internal type from another assembly. A method might not have access to its containing type, its return type, or one of its parameter types.

Apps compiled by using the .NET Native tool chain may throw a MissingMetadataException exception at run time. `MissingMetadataException` is an internal-only exception type derived from TypeAccessException. The exception indicates that metadata needed for the successful execution of an app is not present at run time. You should not use a `try`/`catch` block to handle the exception. Instead, you should determine what metadata is missing and modify your app's runtime directives file to ensure that it is present at run time.

Constructors

Expand table

TypeAccessException()	Initializes a new instance of the TypeAccessException class with a system-supplied message that describes the error.
TypeAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TypeAccessException class with serialized data.
TypeAccessException(String)	Initializes a new instance of the TypeAccessException class with a specified message that describes the error.
TypeAccessException(String, Exception)	Initializes a new instance of the TypeAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message for this exception. (Inherited from TypeLoadException)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

TypeName	Gets the fully qualified name of the type that causes the exception. (Inherited from TypeLoadException)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the class name, method name, resource ID, and additional exception information. (Inherited from TypeLoadException)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeAccessException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the TypeAccessException class.

Overloads

Expand table

TypeAccessException()	Initializes a new instance of the TypeAccessException class with a system-supplied message that describes the error.
TypeAccessException(String)	Initializes a new instance of the TypeAccessException class with a specified message that describes the error.
TypeAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TypeAccessException class with serialized data.
TypeAccessException(String, Exception)	Initializes a new instance of the TypeAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

TypeAccessException()

Initializes a new instance of the TypeAccessException class with a system-supplied message that describes the error.

C#

```
public TypeAccessException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempt to access the type failed." This message takes the current system culture into account.

The following table shows the initial property values for an instance of TypeAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

- Handling and Throwing Exceptions

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeAccessException(String)

Initializes a new instance of the TypeAccessException class with a specified message that describes the error.

```
C#
```

```
public TypeAccessException (string? message);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor must ensure that this string has been localized for the current system culture.

Remarks

The following table shows the initial property values for an instance of TypeAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string specified in `message`.

See also

- Handling and Throwing Exceptions

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeAccessException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the TypeAccessException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected TypeAccessException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object that was transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypeAccessException(String, Exception)

Initializes a new instance of the TypeAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public TypeAccessException (string? message, Exception? inner);
```

Parameters

`message` String

The message that describes the exception. The caller of this constructor must ensure that this string has been localized for the current system culture.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of TypeAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string specified in `message`.

TypeCode Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the type of an object.

```
C#

public enum TypeCode
```

Inheritance Object → ValueType → Enum → TypeCode

Fields

Expand table

Boolean	3	A simple type representing Boolean values of `true` or `false`.
Byte	6	An integral type representing unsigned 8-bit integers with values between 0 and 255.
Char	4	An integral type representing unsigned 16-bit integers with values between 0 and 65535. The set of possible values for the Char type corresponds to the Unicode character set.
DateTime	16	A type representing a date and time value.
DBNull	2	A database null (column) value.
Decimal	15	A simple type representing values ranging from 1.0×10^{-28} to approximately 7.9×10^{28} with 28-29 significant digits.
Double	14	A floating point type representing values ranging from approximately 5.0×10^{-324} to 1.7×10^{308} with a precision of 15-16 digits.
Empty	0	A null reference.
Int16	7	An integral type representing signed 16-bit integers with values between -32768 and 32767.

Int32	9	An integral type representing signed 32-bit integers with values between -2147483648 and 2147483647.
Int64	11	An integral type representing signed 64-bit integers with values between -9223372036854775808 and 9223372036854775807.
Object	1	A general type representing any reference or value type not explicitly represented by another `TypeCode`.
SByte	5	An integral type representing signed 8-bit integers with values between -128 and 127.
Single	13	A floating point type representing values ranging from approximately 1.5×10^{-45} to 3.4×10^{38} with a precision of 7 digits.
String	18	A sealed class type representing Unicode character strings.
UInt16	8	An integral type representing unsigned 16-bit integers with values between 0 and 65535.
UInt32	10	An integral type representing unsigned 32-bit integers with values between 0 and 4294967295.
UInt64	12	An integral type representing unsigned 64-bit integers with values between 0 and 18446744073709551615.

Examples

The following code example demonstrates how the TypeCode enumeration can be used. In a decision block inside the WriteObjectInfo method, the TypeCode of an Object parameter is examined, and an appropriate message is written to the console.

C#

```
static void WriteObjectInfo(object testObject)
{
    TypeCode    typeCode = Type.GetTypeCode( testObject.GetType() );

    switch( typeCode )
    {
        case TypeCode.Boolean:
            Console.WriteLine("Boolean: {0}", testObject);
            break;

        case TypeCode.Double:
            Console.WriteLine("Double: {0}", testObject);
            break;

        default:
            Console.WriteLine("{0}: {1}", typeCode.ToString(), testObject);
```

```
                break;
        }
    }
```

Remarks

Call the GetTypeCode method on classes that implement the IConvertible interface to obtain the type code for an instance of that class.

Otherwise, call an object's GetType method to obtain its Type object, then call the `Type` object's GetTypeCode method to obtain the object's type code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TypedReference Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Describes objects that contain both a managed pointer to a location and a runtime representation of the type that may be stored at that location.

C#

```
[System.CLSCompliant(false)]
public ref struct TypedReference
```

Inheritance Object → ValueType → TypedReference

Attributes CLSCompliantAttribute

Remarks

A typed reference is a type/value combination used for varargs and other support. `TypedReference` is a built-in value type that can be used for parameters and local variables.

Arrays of `TypedReference` objects cannot be created. For example, the following call is invalid:

C#

```
Assembly.Load("mscorlib.dll").GetType("System.TypedReference[]");
```

Methods

Expand table

Equals(Object)	Checks if this object is equal to the specified object.
GetHashCode()	Returns the hash code of this object.
GetTargetType(TypedReference)	Returns the type of the target of the specified `TypedReference`.
MakeTypedReference(Object, FieldInfo[])	Makes a `TypedReference` for a field identified by a specified object and list of field descriptions.
SetTypedReference(TypedReference, Object)	Converts the specified value to a `TypedReference`. This method is not supported.
TargetTypeToken(TypedReference)	Returns the internal metadata type handle for the specified `TypedReference`.
ToObject(TypedReference)	Converts the specified `TypedReference` to an `Object`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

TypedReference.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Checks if this object is equal to the specified object.

C#

```
public override bool Equals (object? o);
```

Parameters

o Object

The object with which to compare the current object.

Returns

Boolean

`true` if this object is equal to the specified object; otherwise, `false`.

Exceptions

NotSupportedException

This method is not implemented.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypedReference.GetTargetType(TypedReference) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the type of the target of the specified `TypedReference`.

```
C#
public static Type GetTargetType (TypedReference value);
```

Parameters

`value` TypedReference

The value whose target's type is to be returned.

Returns

Type

The type of the target of the specified `TypedReference`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypedReference.MakeTypedReference(Object, FieldInfo[]) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Makes a `TypedReference` for a field identified by a specified object and list of field descriptions.

C#

```
public static TypedReference MakeTypedReference (object target,
System.Reflection.FieldInfo[] flds);
```

Parameters

`target` Object

An object that contains the field described by the first element of `flds`.

`flds` FieldInfo[]

A list of field descriptions where each element describes a field that contains the field described by the succeeding element. Each described field must be a value type. The field descriptions must be `RuntimeFieldInfo` objects supplied by the type system.

Returns

TypedReference

A TypedReference for the field described by the last element of `flds`.

Exceptions

ArgumentNullException

`target` or `flds` is `null`.

-or-

An element of `flds` is `null`.

ArgumentException

The `flds` array has no elements.

-or-

An element of `flds` is not a `RuntimeFieldInfo` object.

-or-

The IsInitOnly or IsStatic property of an element of `flds` is `true`.

MissingMemberException

Parameter `target` does not contain the field described by the first element of `flds`, or an element of `flds` describes a field that is not contained in the field described by the succeeding element of `flds`.

-or-

The field described by an element of `flds` is not a value type.

Remarks

The MakeTypedReference method returns a typed reference to some terminal field, where the `target` parameter contains the field described by the first element of `flds`, the field described by the first element of `flds` contains the field described by the second element of `flds`, and so on until the terminal field is reached.

> **Note**
>
> Starting with the .NET Framework 2.0 Service Pack 1, this method can be used to access non-public members if the caller has been granted **ReflectionPermission** with the **ReflectionPermissionFlag.RestrictedMemberAccess** flag and if the grant set of the non-public members is restricted to the caller's grant set, or a subset thereof. (See **Security Considerations for Reflection**.)

To use this functionality, your application should target the .NET Framework 3.5 or later.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypedReference.SetTypedReference(TypedReference, Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the specified value to a `TypedReference`. This method is not supported.

C#

```
public static void SetTypedReference (TypedReference target, object? value);
```

Parameters

`target` TypedReference

The target of the conversion.

`value` Object

The value to be converted.

Exceptions

NotSupportedException

In all cases.

Remarks

This method always throws NotSupportedException.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypedReference.TargetTypeToken(TypedReference) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the internal metadata type handle for the specified `TypedReference`.

```
C#
public static RuntimeTypeHandle TargetTypeToken (TypedReference value);
```

Parameters

`value` TypedReference

The `TypedReference` for which the type handle is requested.

Returns

RuntimeTypeHandle

The internal metadata type handle for the specified `TypedReference`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypedReference.ToObject(TypedReference) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the specified `TypedReference` to an `Object`.

```
C#
public static object ToObject (TypedReference value);
```

Parameters

`value` TypedReference

The `TypedReference` to be converted.

Returns

Object

An Object converted from a `TypedReference`.

Remarks

This might be a boxing operation.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypeInitializationException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown as a wrapper around the exception thrown by the class initializer. This class cannot be inherited.

C#

```
public sealed class TypeInitializationException : SystemException
```

Inheritance Object → Exception → SystemException → TypeInitializationException

Remarks

For more information about this API, see Supplemental API remarks for TypeInitializationException.

Constructors

Expand table

TypeInitializationException(String, Exception)	Initializes a new instance of the TypeInitializationException class with the default error message, the specified type name, and a reference to the inner exception that is the root cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception.

	(Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)
TypeName	Gets the fully qualified name of the type that fails to initialize.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the type name and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)

ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeInitializationException(String, Exception) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the TypeInitializationException class with the default error message, the specified type name, and a reference to the inner exception that is the root cause of this exception.

```
C#

public TypeInitializationException (string? fullTypeName, Exception?
innerException);
```

Parameters

`fullTypeName` String

The fully qualified name of the type that fails to initialize.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of TypeInitializationException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The localized error message string.
TypeName	The name of the type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeInitializationException.TypeName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the fully qualified name of the type that fails to initialize.

C#

```
public string TypeName { get; }
```

Property Value

String

The fully qualified name of the type that fails to initialize.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TypeInitializationException.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the type name and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

TypeLoadException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when type-loading failures occur.

C#

```
public class TypeLoadException : SystemException
```

Inheritance Object → Exception → SystemException → TypeLoadException

Derived System.DllNotFoundException
System.EntryPointNotFoundException
System.TypeAccessException

Remarks

TypeLoadException is thrown when the common language runtime cannot find the assembly, the type within the assembly, or cannot load the type. The Message property contains more detailed information that can help you identify the cause of the exception.

TypeLoadException uses the HRESULT COR_E_TYPELOAD, that has the value 0x80131522.

For a list of initial property values for an instance of TypeLoadException, see the TypeLoadException constructors.

The exact timing of when statically referenced types are loaded is unspecified. This exception may be thrown before the method that references the missing type starts executing.

Constructors

Expand table

TypeLoadException()	Initializes a new instance of the TypeLoadException class.
TypeLoadException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TypeLoadException class with serialized data.
TypeLoadException(String)	Initializes a new instance of the TypeLoadException class with a specified error message.
TypeLoadException(String, Exception)	Initializes a new instance of the TypeLoadException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets the error message for this exception.
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)
TypeName	Gets the fully qualified name of the type that causes the exception.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Sets the SerializationInfo object with the class name, method name, resource ID, and additional exception information.
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions

TypeLoadException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the TypeLoadException class.

Overloads

Expand table

TypeLoadException()	Initializes a new instance of the TypeLoadException class.
TypeLoadException(String)	Initializes a new instance of the TypeLoadException class with a specified error message.
TypeLoadException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TypeLoadException class with serialized data.
TypeLoadException(String, Exception)	Initializes a new instance of the TypeLoadException class with a specified error message and a reference to the inner exception that is the cause of this exception.

TypeLoadException()

Initializes a new instance of the TypeLoadException class.

C#

```
public TypeLoadException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "A failure has occurred while loading a type." This message takes into account the current system culture.

The following table shows the initial property values for an instance of TypeLoadException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeLoadException(String)

Initializes a new instance of the TypeLoadException class with a specified error message.

C#

```
public TypeLoadException (string? message);
```

Parameters

`message` String

The message that describes the error.

Examples

The following code example demonstrates the TypeLoadException(String) constructor. It contains a method that generates a TypeLoadException with a custom message, and displays the error message to the console.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      try {
         // Call a method that throws an exception.
         TypeLoadExceptionDemoClass.GenerateException();
      }
      catch (TypeLoadException e) {
         Console.WriteLine("TypeLoadException:\n   {0}", e.Message);
      }
   }
}

class TypeLoadExceptionDemoClass
{
   public static bool GenerateException()
   {
      // Throw a TypeLoadException with a custom defined message.
      throw new TypeLoadException("This is a custom TypeLoadException
error message.");
   }
}
// The example displays the following output:
//       TypeLoadException:
//          This is a custom TypeLoadException error message.
```

Remarks

The content of the `message` parameter should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of TypeLoadException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TypeLoadException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the TypeLoadException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected TypeLoadException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` object is `null`.

Examples

The following example generates an exception, and serializes the exception data to a file, and then reconstitutes the exception. For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.Reflection;
using System.Runtime.Serialization;
using System.Runtime.Serialization.Formatters.Soap;
using System.IO;

class GetObjectDataDemo
{
   public static void Main()
   {
      // Get a reference to the assembly mscorlib.dll, which is always
      // loaded. (System.String is defined in mscorlib.)
      Assembly mscorlib = typeof(string).Assembly;

      try
      {
         Console.WriteLine ("Attempting to load a type not present in the
assembly 'mscorlib'");
         // This loading of invalid type raises a TypeLoadException
         Type myType = mscorlib.GetType("System.NonExistentType", true);
      }
      catch (TypeLoadException)
      {
```

```
         // Serialize the exception to disk and reconstitute it.
         System.DateTime ErrorDatetime = DateTime.Now;
         Console.WriteLine("A TypeLoadException has been raised.");

         // Create MyTypeLoadException instance with current time.
         MyTypeLoadException myException = new
MyTypeLoadException(ErrorDatetime);
         IFormatter myFormatter = new SoapFormatter();
         Stream myFileStream = new FileStream("typeload.xml",
FileMode.Create, FileAccess.Write, FileShare.None);
         Console.WriteLine("Serializing the TypeLoadException with
DateTime as " + ErrorDatetime);

         // Serialize the MyTypeLoadException instance to a file.
         myFormatter.Serialize(myFileStream, myException);
         myFileStream.Close();

         Console.WriteLine("Deserializing the Exception.");
         myFileStream = new FileStream("typeload.xml", FileMode.Open,
FileAccess.Read, FileShare.None);

         // Deserialize and reconstitute the instance from file.
         myException = (MyTypeLoadException)
myFormatter.Deserialize(myFileStream);
         myFileStream.Close();
         Console.WriteLine("Deserialized exception has ErrorDateTime = "
+ myException.ErrorDateTime);
      }
   }
}

// This class overrides the GetObjectData method and initializes
// its data with current time.

[Serializable]
public class MyTypeLoadException : TypeLoadException
{
   private System.DateTime _errorDateTime = DateTime.Now;
   public DateTime ErrorDateTime { get { return _errorDateTime; }}

   public MyTypeLoadException(DateTime myDateTime)
   {
      _errorDateTime = myDateTime;
   }

   protected MyTypeLoadException(SerializationInfo sInfo,
StreamingContext sContext)
       : base(sInfo, sContext)
   {
      // Reconstitute the deserialized information into the instance.
      _errorDateTime = sInfo.GetDateTime("ErrorDate");
   }

   public override void GetObjectData(SerializationInfo sInfo,
StreamingContext sContext)
```

```
    {
        base.GetObjectData(sInfo, sContext);
        // Add a value to the Serialization information.
        sInfo.AddValue("ErrorDate", ErrorDateTime);
    }
}
```

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypeLoadException(String, Exception)

Initializes a new instance of the TypeLoadException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public TypeLoadException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Examples

The following code example demonstrates the TypeLoadException(String, Exception) constructor. It contains a method that generates a TypeLoadException, catches that exception, and throws a new TypeLoadException with a custom message, including the original TypeLoadException as the inner exception.

C#

```
using System;
using System.Runtime.InteropServices;

public class TypeLoadException_Constructor3
{
   public static void Main()
   {
      Console.WriteLine("Calling a method in a non-existent DLL which
triggers a TypeLoadException.");
      try
      {
         TypeLoadExceptionDemoClass3.GenerateException();
      }
      catch (TypeLoadException e)
      {
         Console.WriteLine ("TypeLoadException: \n\tError Message = " +
e.Message);
         Console.WriteLine ("TypeLoadException: \n\tInnerException
Message = " + e.InnerException.Message );
      }
      catch (Exception e)
      {
         Console.WriteLine ("Exception: \n\tError Message = " +
e.Message);
      }
   }
}

class TypeLoadExceptionDemoClass3
{
   // A call to this method will raise a TypeLoadException.
   [DllImport("NonExistentDLL.DLL", EntryPoint="MethodNotExists")]
   public static extern void NonExistentMethod();

   public static void GenerateException()
```

```
    {
        try
        {
            NonExistentMethod();
        }
        catch (TypeLoadException e)
        {
            // Rethrow exception with the exception as inner exception
            throw new TypeLoadException("This exception was raised due to a
call to an invalid method.", e);
        }
    }
}
```

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of TypeLoadException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

TypeLoadException.Message Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the error message for this exception.

C#

```
public override string Message { get; }
```

Property Value

String

The error message string.

Examples

The following example attempts to load a non-existent type from the mscorlib assembly. The resulting exception is caught, and the TypeName and Message values are displayed. For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.Reflection;

public class TypeLoadException_TypeName
{
   public static void Main()
   {
      // Get a reference to the assembly mscorlib.dll, which is always
      // loaded. (System.String is defined in mscorlib.)
      Assembly mscorlib = typeof(string).Assembly;

      try
      {
```

```
            Console.WriteLine("Attempting to load a type that does not exist in
mscorlib.");
            // The boolean parameter causes an exception to be thrown if the
            // type is not found.
            Type myType = mscorlib.GetType("System.NonExistentType", true);
        }
        catch (TypeLoadException ex)
        {
            // Display the name of the type that was not found, and the
            // exception message.
            Console.WriteLine("TypeLoadException was caught. Type = '{0}'.",
                ex.TypeName);
            Console.WriteLine("Error Message = '{0}'", ex.Message);
        }
    }
}
/*
 This code example produces output similar to the following:

Attempting to load a type that does not exist in mscorlib.
TypeLoadException was caught. Type = 'System.NonExistentType'
Error Message = 'Could not load type System.NonExistentType from assembly
mscorl
ib, Version=1.0.5000.0, Culture=neutral, PublicKeyToken=b77a5c561934e089.'
 */
```

Remarks

This property overrides Message. The error message should be localized.

This property is read-only.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

TypeLoadException.TypeName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the fully qualified name of the type that causes the exception.

C#

```
public string TypeName { get; }
```

Property Value

String

The fully qualified type name.

Examples

The following example attempts to load a non-existent type from the mscorlib assembly. The resulting exception is caught, and the TypeName and Message values are displayed. For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.Reflection;

public class TypeLoadException_TypeName
{
   public static void Main()
   {
      // Get a reference to the assembly mscorlib.dll, which is always
      // loaded. (System.String is defined in mscorlib.)
      Assembly mscorlib = typeof(string).Assembly;

      try
      {
```

```
            Console.WriteLine("Attempting to load a type that does not exist in
mscorlib.");
            // The boolean parameter causes an exception to be thrown if the
            // type is not found.
            Type myType = mscorlib.GetType("System.NonExistentType", true);
        }
        catch (TypeLoadException ex)
        {
            // Display the name of the type that was not found, and the
            // exception message.
            Console.WriteLine("TypeLoadException was caught. Type = '{0}'.",
                ex.TypeName);
            Console.WriteLine("Error Message = '{0}'", ex.Message);
        }
    }
}
/*
 This code example produces output similar to the following:

Attempting to load a type that does not exist in mscorlib.
TypeLoadException was caught. Type = 'System.NonExistentType'
Error Message = 'Could not load type System.NonExistentType from assembly
mscorl
ib, Version=1.0.5000.0, Culture=neutral, PublicKeyToken=b77a5c561934e089.'
 */
```

Notes to Inheritors

When overriding TypeName in a derived class, be sure to call the base class's TypeName property.

This property is read-only.

Applies to

TypeLoadException.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Sets the SerializationInfo object with the class name, method name, resource ID, and additional exception information.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public override void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `info` object is `null`.

Examples

The following example generates an exception, and serializes the exception data to a file, and then reconstitutes the exception. For this code example to run, you must provide the fully qualified assembly name. For information about how to obtain the fully qualified assembly name, see Assembly Names.

C#

```
using System;
using System.Reflection;
using System.Runtime.Serialization;
using System.Runtime.Serialization.Formatters.Soap;
using System.IO;

class GetObjectDataDemo
{
   public static void Main()
   {
      // Get a reference to the assembly mscorlib.dll, which is always
      // loaded. (System.String is defined in mscorlib.)
      Assembly mscorlib = typeof(string).Assembly;

      try
      {
         Console.WriteLine ("Attempting to load a type not present in the
assembly 'mscorlib'");
         // This loading of invalid type raises a TypeLoadException
         Type myType = mscorlib.GetType("System.NonExistentType", true);
      }
      catch (TypeLoadException)
      {
         // Serialize the exception to disk and reconstitute it.
         System.DateTime ErrorDatetime = DateTime.Now;
         Console.WriteLine("A TypeLoadException has been raised.");

         // Create MyTypeLoadException instance with current time.
         MyTypeLoadException myException = new
MyTypeLoadException(ErrorDatetime);
         IFormatter myFormatter = new SoapFormatter();
         Stream myFileStream = new FileStream("typeload.xml",
FileMode.Create, FileAccess.Write, FileShare.None);
         Console.WriteLine("Serializing the TypeLoadException with DateTime
as " + ErrorDatetime);
```

```
         // Serialize the MyTypeLoadException instance to a file.
         myFormatter.Serialize(myFileStream, myException);
         myFileStream.Close();

         Console.WriteLine("Deserializing the Exception.");
         myFileStream = new FileStream("typeload.xml", FileMode.Open,
FileAccess.Read, FileShare.None);

         // Deserialize and reconstitute the instance from file.
         myException = (MyTypeLoadException)
myFormatter.Deserialize(myFileStream);
         myFileStream.Close();
         Console.WriteLine("Deserialized exception has ErrorDateTime = " +
myException.ErrorDateTime);
      }
   }
}

// This class overrides the GetObjectData method and initializes
// its data with current time.

[Serializable]
public class MyTypeLoadException : TypeLoadException
{
   private System.DateTime _errorDateTime = DateTime.Now;
   public DateTime ErrorDateTime { get { return _errorDateTime; }}

   public MyTypeLoadException(DateTime myDateTime)
   {
      _errorDateTime = myDateTime;
   }

   protected MyTypeLoadException(SerializationInfo sInfo, StreamingContext
sContext)
       : base(sInfo, sContext)
   {
      // Reconstitute the deserialized information into the instance.
      _errorDateTime = sInfo.GetDateTime("ErrorDate");
   }

   public override void GetObjectData(SerializationInfo sInfo,
StreamingContext sContext)
   {
      base.GetObjectData(sInfo, sContext);
      // Add a value to the Serialization information.
      sInfo.AddValue("ErrorDate", ErrorDateTime);
   }
}
```

Remarks

GetObjectData sets a SerializationInfo with all the exception object data targeted for serialization. During deserialization, the exception object is reconstituted from the SerializationInfo transmitted over the stream.

For more information, see XML and SOAP Serialization.

Applies to

TypeUnloadedException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when there is an attempt to access an unloaded class.

C#

```
public class TypeUnloadedException : SystemException
```

Inheritance Object → Exception → SystemException → TypeUnloadedException

Remarks

TypeUnloadedException uses the HRESULT COR_E_TYPEUNLOADED, that has the value 0x80131013.

For a list of initial property values for an instance of TypeUnloadedException, see the TypeUnloadedException constructors.

Constructors

Expand table

TypeUnloadedException()	Initializes a new instance of the TypeUnloadedException class.
TypeUnloaded Exception(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TypeUnloadedException class with serialized data.
TypeUnloadedException(String)	Initializes a new instance of the TypeUnloadedException class with a specified error message.
TypeUnloadedException(String, Exception)	Initializes a new instance of the TypeUnloadedException class with a specified error message and a reference to the

	inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)

GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypeUnloadedException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes new instance of the TypeUnloadedException class.

Overloads

Expand table

TypeUnloadedException()	Initializes a new instance of the TypeUnloadedException class.
TypeUnloadedException(String)	Initializes a new instance of the TypeUnloadedException class with a specified error message.
TypeUnloadedException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the TypeUnloadedException class with serialized data.
TypeUnloadedException(String, Exception)	Initializes a new instance of the TypeUnloadedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

TypeUnloadedException()

Initializes a new instance of the TypeUnloadedException class.

C#

```
public TypeUnloadedException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Type has been unloaded." This message takes into account the current system culture.

The following table shows the initial property values for an instance of TypeUnloadedException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypeUnloadedException(String)

Initializes a new instance of the TypeUnloadedException class with a specified error message.

C#

```
public TypeUnloadedException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter should be understandable to the end user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of TypeUnloadedException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypeUnloadedException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the TypeUnloadedException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected TypeUnloadedException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The object that holds the serialized object data.

`context` StreamingContext

The contextual information about the source or destination.

Attributes ObsoleteAttribute

Remarks

This constructor is called during deserialization to reconstitute the exception object transmitted over a stream. For more information, see XML and SOAP Serialization.

See also

- XML and SOAP Serialization

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

TypeUnloadedException(String, Exception)

Initializes a new instance of the TypeUnloadedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public TypeUnloadedException (string? message, Exception?
innerException);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`innerException` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception can include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of TypeUnloadedException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Constructors

Expand table

UInt128(UInt64, UInt64)	Initializes a new instance of the UInt128 struct.

Properties

Expand table

MaxValue	Gets the maximum value of the current type.
MinValue	Gets the minimum value of the current type.
One	Gets the value `1` for the type.
Zero	Gets the value `0` for the type.

Methods

Expand table

Clamp(UInt128, UInt128, UInt128)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(UInt128)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall

	outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(UInt128, UInt128)	Computes the quotient and remainder of two values.
Equals(Object)	Determines whether the specified object is equal to the current object.
Equals(UInt128)	Indicates whether the current object is equal to another object of the same type.
GetHashCode()	Serves as the default hash function.
IsEvenInteger(UInt128)	Determines if a value represents an even integral number.
IsOddInteger(UInt128)	Determines if a value represents an odd integral number.
IsPow2(UInt128)	Determines if a value is a power of two.
LeadingZeroCount(UInt128)	Computes the number of leading zeros in a value.
Log2(UInt128)	Computes the log2 of a value.
Max(UInt128, UInt128)	Compares two values to compute which is greater.
Min(UInt128, UInt128)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Parses a span of characters into a value.
Parse(String)	Parses a string into a value.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(String, NumberStyles)	Parses a string into a value.

Parse(String, NumberStyles, IFormatProvider)	Parses a string into a value.
PopCount(UInt128)	Computes the number of bits that are set in a value.
RotateLeft(UInt128, Int32)	Rotates a value left by a given amount.
RotateRight(UInt128, Int32)	Rotates a value right by a given amount.
Sign(UInt128)	Computes the sign of a value.
ToString()	Returns a string that represents the current object.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
TrailingZeroCount(UInt128)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, UInt128)	Tries to convert a UTF-8 character span containing the string representation of a number to its 128-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt128)	Tries to parse a span of characters into a value.

TryParse(ReadOnlySpan<Char>, UInt128)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, UInt128)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, UInt128)	Tries to parse a string into a value.
TryParse(String, UInt128)	Tries to parse a string into a value.

Operators

Expand table

Addition(UInt128, UInt128)	Adds two values together to compute their sum.
BitwiseAnd(UInt128, UInt128)	Computes the bitwise-and of two values.
BitwiseOr(UInt128, UInt128)	Computes the bitwise-or of two values.
CheckedAddition(UInt128, UInt128)	Adds two values together to compute their sum.
CheckedDecrement(UInt128)	Decrements a value.
CheckedDivision(UInt128, UInt128)	Divides two values together to compute their quotient.
CheckedExplicit(Double)	
CheckedExplicit(Int16)	
CheckedExplicit(Int32)	
CheckedExplicit(Int64)	
CheckedExplicit(IntPtr)	
CheckedExplicit(SByte)	
CheckedExplicit(Single)	
CheckedExplicit(UInt128)	
CheckedIncrement(UInt128)	Increments a value.
CheckedMultiply(UInt128, UInt128)	Multiplies two values together to compute their product.
CheckedSubtraction(UInt128, UInt128)	Subtracts two values to compute their difference.

CheckedUnaryNegation(UInt128)	Computes the unary negation of a value.
Decrement(UInt128)	Decrements a value.
Division(UInt128, UInt128)	Divides two values together to compute their quotient.
Equality(UInt128, UInt128)	Compares two values to determine equality.
ExclusiveOr(UInt128, UInt128)	Computes the exclusive-or of two values.
Explicit(Decimal to UInt128)	Explicitly converts a Decimal value to a 128-bit unsigned integer.
Explicit(Double to UInt128)	Explicitly converts a Double value to a 128-bit unsigned integer.
Explicit(Int16 to UInt128)	Explicitly converts a Int16 value to a 128-bit unsigned integer.
Explicit(Int32 to UInt128)	Explicitly converts a Int32 value to a 128-bit unsigned integer.
Explicit(Int64 to UInt128)	Explicitly converts a Int64 value to a 128-bit unsigned integer.
Explicit(IntPtr to UInt128)	Explicitly converts a IntPtr value to a 128-bit unsigned integer.
Explicit(SByte to UInt128)	Explicitly converts a SByte value to a 128-bit unsigned integer.
Explicit(Single to UInt128)	Explicitly converts a Single value to a 128-bit unsigned integer.
Explicit(UInt128 to Byte)	Explicitly converts a 128-bit unsigned integer to a Byte value.
Explicit(UInt128 to Char)	Explicitly converts a 128-bit unsigned integer to a Char value.
Explicit(UInt128 to Decimal)	Explicitly converts a 128-bit unsigned integer to a Decimal value.
Explicit(UInt128 to Double)	Explicitly converts a 128-bit unsigned integer to a Double value.
Explicit(UInt128 to Half)	Explicitly converts a 128-bit unsigned integer to a Half value.
Explicit(UInt128 to Int128)	Explicitly converts a 128-bit unsigned integer to a Int128 value.

Explicit(UInt128 to Int16)	Explicitly converts a 128-bit unsigned integer to a Int16 value.
Explicit(UInt128 to Int32)	Explicitly converts a 128-bit unsigned integer to a Int32 value.
Explicit(UInt128 to Int64)	Explicitly converts a 128-bit unsigned integer to a Int64 value.
Explicit(UInt128 to IntPtr)	Explicitly converts a 128-bit unsigned integer to a IntPtr value.
Explicit(UInt128 to SByte)	Explicitly converts a 128-bit unsigned integer to a SByte value.
Explicit(UInt128 to Single)	Explicitly converts a 128-bit unsigned integer to a Single value.
Explicit(UInt128 to UInt16)	Explicitly converts a 128-bit unsigned integer to a UInt16 value.
Explicit(UInt128 to UInt32)	Explicitly converts a 128-bit unsigned integer to a UInt32 value.
Explicit(UInt128 to UInt64)	Explicitly converts a 128-bit unsigned integer to a UInt64 value.
Explicit(UInt128 to UIntPtr)	Explicitly converts a 128-bit unsigned integer to a UIntPtr value.
GreaterThan(UInt128, UInt128)	Compares two values to determine which is greater.
GreaterThanOrEqual(UInt128, UInt128)	Compares two values to determine which is greater or equal.
Implicit(Byte to UInt128)	Implicitly converts a Byte value to a 128-bit unsigned integer.
Implicit(Char to UInt128)	Implicitly converts a Char value to a 128-bit unsigned integer.
Implicit(UInt16 to UInt128)	Implicitly converts a UInt16 value to a 128-bit unsigned integer.
Implicit(UInt32 to UInt128)	Implicitly converts a UInt32 value to a 128-bit unsigned integer.
Implicit(UInt64 to UInt128)	Implicitly converts a UInt64 value to a 128-bit unsigned integer.
Implicit(UIntPtr to UInt128)	Implicitly converts a UIntPtr value to a 128-bit unsigned integer.

Increment(UInt128)	Increments a value.
Inequality(UInt128, UInt128)	Compares two values to determine inequality.
LeftShift(UInt128, Int32)	Shifts a value left by a given amount.
LessThan(UInt128, UInt128)	Compares two values to determine which is less.
LessThanOrEqual(UInt128, UInt128)	Compares two values to determine which is less or equal.
Modulus(UInt128, UInt128)	Divides two values together to compute their modulus or remainder.
Multiply(UInt128, UInt128)	Multiplies two values together to compute their product.
OnesComplement(UInt128)	Computes the ones-complement representation of a given value.
RightShift(UInt128, Int32)	Shifts a value right by a given amount.
Subtraction(UInt128, UInt128)	Subtracts two values to compute their difference.
UnaryNegation(UInt128)	Computes the unary negation of a value.
UnaryPlus(UInt128)	Computes the unary plus of a value.
UnsignedRightShift(UInt128, Int32)	Shifts a value right by a given amount.

Explicit Interface Implementations

Expand table

IAdditiveIdentity<UInt128,UInt128>.Additive Identity	Gets the additive identity of the current type.
IBinaryInteger<UInt128>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<UInt128>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<UInt128>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, UInt128)	
IBinaryInteger<UInt128>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, UInt128)	
IBinaryInteger<UInt128>.TryWriteBig Endian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.

IBinaryInteger<UInt128>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<UInt128>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IMultiplicativeIdentity<UInt128,UInt128>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
INumber<UInt128>.CopySign(UInt128, UInt128)	Copies the sign of a value to the sign of another value.
INumber<UInt128>.MaxNumber(UInt128, UInt128)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<UInt128>.MinNumber(UInt128, UInt128)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<UInt128>.Abs(UInt128)	Computes the absolute of a value.
INumberBase<UInt128>.IsCanonical(UInt128)	Determines if a value is in its canonical representation.
INumberBase<UInt128>.IsComplexNumber(UInt128)	Determines if a value represents a complex number.
INumberBase<UInt128>.IsFinite(UInt128)	Determines if a value is finite.
INumberBase<UInt128>.IsImaginaryNumber(UInt128)	Determines if a value represents a pure imaginary number.
INumberBase<UInt128>.IsInfinity(UInt128)	Determines if a value is infinite.
INumberBase<UInt128>.IsInteger(UInt128)	Determines if a value represents an integral number.
INumberBase<UInt128>.IsNaN(UInt128)	Determines if a value is NaN.
INumberBase<UInt128>.IsNegative(UInt128)	Determines if a value is negative.
INumberBase<UInt128>.IsNegativeInfinity(UInt128)	Determines if a value is negative infinity.
INumberBase<UInt128>.IsNormal(UInt128)	Determines if a value is normal.
INumberBase<UInt128>.IsPositive(UInt128)	Determines if a value is positive.
INumberBase<UInt128>.IsPositiveInfinity(UInt128)	Determines if a value is positive infinity.

INumberBase<UInt128>.IsRealNumber(UInt128)	Determines if a value represents a real number.
INumberBase<UInt128>.IsSubnormal(UInt128)	Determines if a value is subnormal.
INumberBase<UInt128>.IsZero(UInt128)	Determines if a value is zero.
INumberBase<UInt128>.MaxMagnitude(UInt128, UInt128)	Compares two values to compute which is greater.
INumberBase<UInt128>.MaxMagnitudeNumber(UInt128, UInt128)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt128>.MinMagnitude(UInt128, UInt128)	Compares two values to compute which is lesser.
INumberBase<UInt128>.MinMagnitudeNumber(UInt128, UInt128)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt128>.Radix	Gets the radix, or base, for the type.
INumberBase<UInt128>.TryConvertFromChecked<TOther>(TOther, UInt128)	
INumberBase<UInt128>.TryConvertFromSaturating<TOther>(TOther, UInt128)	
INumberBase<UInt128>.TryConvertFromTruncating<TOther>(TOther, UInt128)	
INumberBase<UInt128>.TryConvertToChecked<TOther>(UInt128, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<UInt128>.TryConvertToSaturating<TOther>(UInt128, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<UInt128>.TryConvertToTruncating<TOther>(UInt128, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

Applies to

Product	Versions
.NET	7, 8, 9

UInt128(UInt64, UInt64) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of the UInt128 struct.

C#

```
[System.CLSCompliant(false)]
public UInt128 (ulong upper, ulong lower);
```

Parameters

upper UInt64

The upper 64-bits of the 128-bit value.

lower UInt64

The lower 64-bits of the 128-bit value.

Attributes CLSCompliantAttribute

Applies to

Product	Versions
.NET	7, 8, 9

UInt128.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
public static UInt128 MaxValue { get; }
```

Property Value

UInt128

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
public static UInt128 MinValue { get; }
```

Property Value

UInt128

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

UInt128.One Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `1` for the type.

```
C#
public static UInt128 One { get; }
```

Property Value

UInt128

Implements

One

Applies to

Product	Versions
.NET	7, 8, 9

UInt128.Clamp(UInt128, UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static UInt128 Clamp (UInt128 value, UInt128 min, UInt128 max);
```

Parameters

`value` UInt128

The value to clamp.

`min` UInt128

The inclusive minimum to which `value` should clamp.

`max` UInt128

The inclusive maximum to which `value` should clamp.

Returns

UInt128

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(UInt128)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

CompareTo(Object)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare with this instance.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CompareTo(UInt128)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (UInt128 value);
```

Parameters

`value` UInt128

An object to compare with this instance.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static UInt128 CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt128

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static UInt128 CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

UInt128

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static UInt128 CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

TOther

The type of `value`.

Parameters

value TOther

The value which is used to create the instance of `TSelf`.

Returns

UInt128

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.DivRem(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

C#

```
public static (UInt128 Quotient, UInt128 Remainder) DivRem (UInt128 left,
UInt128 right);
```

Parameters

left UInt128

The value which `right` divides.

right UInt128

The value which divides `left`.

Returns

ValueTuple<UInt128,UInt128>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(UInt128)	Indicates whether the current object is equal to another object of the same type.
Equals(Object)	Determines whether the specified object is equal to the current object.

Equals(UInt128)

Indicates whether the current object is equal to another object of the same type.

C#

```
public bool Equals (UInt128 other);
```

Parameters

other UInt128

An object to compare with this object.

Returns

Boolean

`true` if the current object is equal to the `other` parameter; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Equals(Object)

Determines whether the specified object is equal to the current object.

```
C#
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare with the current object.

Returns

Boolean

`true` if the specified object is equal to the current object; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Serves as the default hash function.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A hash code for the current object.

Applies to

Product	Versions
.NET	7, 8, 9

UInt128.IsEvenInteger(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.IsOddInteger(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

UInt128.IsPow2(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

```
C#
public static bool IsPow2 (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.LeadingZeroCount(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

```
C#
public static UInt128 LeadingZeroCount (UInt128 value);
```

Parameters

`value` UInt128

The value whose leading zeroes are to be counted.

Returns

UInt128

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Log2(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static UInt128 Log2 (UInt128 value);
```

Parameters

`value` UInt128

The value whose log2 is to be computed.

Returns

UInt128

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

UInt128.Max(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static UInt128 Max (UInt128 x, UInt128 y);
```

Parameters

x UInt128

The value to compare with `y`.

y UInt128

The value to compare with `x`.

Returns

UInt128

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Min(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static UInt128 Min (UInt128 x, UInt128 y);
```

Parameters

x UInt128

The value to compare with `y`.

y UInt128

The value to compare with `x`.

Returns

UInt128

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String)	Parses a string into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, NumberStyles)	Parses a string into a value.
Parse(String, IFormatProvider)	Parses a string into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Parses a span of characters into a value.
Parse(String, NumberStyles, IFormatProvider)	Parses a string into a value.

Parse(String)

Parses a string into a value.

C#

```
public static UInt128 Parse (string s);
```

Parameters

s String

A string containing a number to parse.

Returns

UInt128

The result of parsing `s`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static UInt128 Parse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt128

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static UInt128 Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt128

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, NumberStyles)

Parses a string into a value.

```
C#

public static UInt128 Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string containing a number to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

Returns

UInt128

The result of parsing `s`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, IFormatProvider)

Parses a string into a value.

```
C#

public static UInt128 Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt128

The result of parsing `s`.

Implements

Parse(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static UInt128 Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt128

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static UInt128 Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt128

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, NumberStyles, IFormatProvider)

Parses a string into a value.

C#

```
public static UInt128 Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

The string to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt128

The result of parsing `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.PopCount(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static UInt128 PopCount (UInt128 value);
```

Parameters

`value` UInt128

The value whose set bits are to be counted.

Returns

UInt128

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt128.RotateLeft(UInt128, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static UInt128 RotateLeft (UInt128 value, int rotateAmount);
```

Parameters

`value` UInt128

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

UInt128

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.RotateRight(UInt128, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

C#

```
public static UInt128 RotateRight (UInt128 value, int rotateAmount);
```

Parameters

`value` UInt128

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

UInt128

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.Sign(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (UInt128 value);
```

Parameters

`value` UInt128

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
ToString()	Returns a string that represents the current object.

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

C#

```
public string ToString (string? format);
```

Parameters

`format` String

The format to use, or a `null` reference to use the default format defined for the type of the IFormattable implementation.

Returns

String

The string representation of the value of this instance as specified by `format`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ToString(String, IFormatProvider)

Formats the value of the current instance using the specified format.

```
C#
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

The format to use, or a `null` reference to use the default format defined for the type of the IFormattable implementation.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

ToString()

Returns a string that represents the current object.

```
C#
```

```
public override string ToString ();
```

Returns

String

A string that represents the current object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.TrailingZeroCount(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static UInt128 TrailingZeroCount (UInt128 value);
```

Parameters

`value` UInt128

The value whose trailing zeroes are to be counted.

Returns

UInt128

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(ReadOnlySpan<Char>, UInt128)	Tries to parse a span of characters into a value.
TryParse(String, UInt128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt128)	Tries to parse a string into a value.
TryParse(String, IFormatProvider, UInt128)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt128)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt128)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Byte>, UInt128)	Tries to convert a UTF-8 character span containing the string representation of a number to its 128-bit unsigned integer equivalent.
TryParse(String, NumberStyles, IFormatProvider, UInt128)	Tries to parse a string into a value.

TryParse(ReadOnlySpan<Char>, UInt128)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, out UInt128 result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

result UInt128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, UInt128)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, out UInt128 result);
```

Parameters

s String

The string to parse.

result UInt128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt128)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out UInt128 result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt128

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt128)

Tries to parse a string into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out UInt128 result);
```

Parameters

s ReadOnlySpan<Char>

The string to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

result UInt128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, UInt128)

Tries to parse a string into a value.

C#

```
public static bool TryParse (string? s, IFormatProvider? provider, out
UInt128 result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt128)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
UInt128 result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt128

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt128)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
UInt128 result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, UInt128)

Tries to convert a UTF-8 character span containing the string representation of a number to its 128-bit unsigned integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out UInt128
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` UInt128

When this method returns, contains the 128-bit unsigned integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, NumberStyles, IFormatProvider, UInt128)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out UInt128 result);
```

Parameters

`s` String

The string to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `s`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt128

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.Addition(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#
public static UInt128 operator + (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to which `right` is added.

`right` UInt128

The value which is added to `left`.

Returns

UInt128

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.BitwiseAnd(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#
public static UInt128 operator & (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to `and` with `right`.

`right` UInt128

The value to `and` with `left`.

Returns

UInt128

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.BitwiseOr(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#
public static UInt128 operator | (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to `or` with `right`.

`right` UInt128

The value to `or` with `left`.

Returns

UInt128

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CheckedAddition(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#
public static UInt128 op_CheckedAddition (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to which `right` is added.

`right` UInt128

The value which is added to `left`.

Returns

UInt128

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CheckedDecrement(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
public static UInt128 op_CheckedDecrement (UInt128 value);
```

Parameters

`value` UInt128

The value to decrement.

Returns

UInt128

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CheckedDivision(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their quotient.

```
C#
public static UInt128 op_CheckedDivision (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value which `right` divides.

`right` UInt128

The value which divides `left`.

Returns

UInt128

The quotient of `left` divided-by `right`.

Implements

CheckedDivision(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.CheckedExplicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CheckedExplicit(UInt128)
CheckedExplicit(Single)
CheckedExplicit(SByte)
CheckedExplicit(IntPtr)
CheckedExplicit(Int16)
CheckedExplicit(Int32)
CheckedExplicit(Double)
CheckedExplicit(Int64)

CheckedExplicit(UInt128)

C#

```
public static byte op_CheckedExplicit (UInt128 value);
```

Parameters

`value` UInt128

Returns

Byte

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Single)

C#

```
public static UInt128 op_CheckedExplicit (float value);
```

Parameters

`value` Single

Returns

UInt128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(SByte)

> Important
>
> This API is not CLS-compliant.

C#

```
[System.CLSCompliant(false)]
public static UInt128 op_CheckedExplicit (sbyte value);
```

Parameters

`value` SByte

Returns

UInt128

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(IntPtr)

C#

```
public static UInt128 op_CheckedExplicit (IntPtr value);
```

Parameters

`value` IntPtr

Returns

UInt128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Int16)

```
C#
public static UInt128 op_CheckedExplicit (short value);
```

Parameters

`value` Int16

Returns

UInt128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Int32)

```
C#
public static UInt128 op_CheckedExplicit (int value);
```

Parameters

`value` Int32

Returns

UInt128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Double)

```
C#

public static UInt128 op_CheckedExplicit (double value);
```

Parameters

`value` Double

Returns

UInt128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

CheckedExplicit(Int64)

```
C#

public static UInt128 op_CheckedExplicit (long value);
```

Parameters

`value` Int64

Returns

UInt128

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.CheckedIncrement(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
public static UInt128 op_CheckedIncrement (UInt128 value);
```

Parameters

`value` UInt128

The value to increment.

Returns

UInt128

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CheckedMultiply(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

C#

```
public static UInt128 op_CheckedMultiply (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value which `right` multiplies.

`right` UInt128

The value which multiplies `left`.

Returns

UInt128

The product of `left` multiplied-by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.CheckedSubtraction(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#
public static UInt128 op_CheckedSubtraction (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value from which `right` is subtracted.

`right` UInt128

The value which is subtracted from `left`.

Returns

UInt128

The difference of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.CheckedUnaryNegation(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
public static UInt128 op_CheckedUnaryNegation (UInt128 value);
```

Parameters

`value` UInt128

The value for which to compute the unary negation.

Returns

UInt128

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Decrement(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
public static UInt128 operator -- (UInt128 value);
```

Parameters

`value` UInt128

The value to decrement.

Returns

UInt128

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.Division(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their quotient.

```
C#
public static UInt128 operator / (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value which `right` divides.

`right` UInt128

The value which divides `left`.

Returns

UInt128

The quotient of `left` divided-by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Equality(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#
public static bool operator == (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to compare with `right`.

`right` UInt128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.ExclusiveOr(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#
public static UInt128 operator ^ (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to xor with `right`.

`right` UInt128

The value to xor with `left`.

Returns

UInt128

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Explicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Explicit(UInt128 to UIntPtr)	Explicitly converts a 128-bit unsigned integer to a UIntPtr value.
Explicit(UInt128 to UInt64)	Explicitly converts a 128-bit unsigned integer to a UInt64 value.
Explicit(UInt128 to UInt32)	Explicitly converts a 128-bit unsigned integer to a UInt32 value.
Explicit(UInt128 to UInt16)	Explicitly converts a 128-bit unsigned integer to a UInt16 value.
Explicit(UInt128 to Single)	Explicitly converts a 128-bit unsigned integer to a Single value.
Explicit(UInt128 to SByte)	Explicitly converts a 128-bit unsigned integer to a SByte value.
Explicit(UInt128 to IntPtr)	Explicitly converts a 128-bit unsigned integer to a IntPtr value.
Explicit(UInt128 to Int64)	Explicitly converts a 128-bit unsigned integer to a Int64 value.
Explicit(UInt128 to Int32)	Explicitly converts a 128-bit unsigned integer to a Int32 value.
Explicit(UInt128 to Int128)	Explicitly converts a 128-bit unsigned integer to a Int128 value.
Explicit(UInt128 to Half)	Explicitly converts a 128-bit unsigned integer to a Half value.
Explicit(UInt128 to Int16)	Explicitly converts a 128-bit unsigned integer to a Int16 value.
Explicit(UInt128 to Decimal)	Explicitly converts a 128-bit unsigned integer to a Decimal value.
Explicit(Decimal to UInt128)	Explicitly converts a Decimal value to a 128-bit unsigned integer.
Explicit(UInt128 to Double)	Explicitly converts a 128-bit unsigned integer to a Double value.
Explicit(Int16 to UInt128)	Explicitly converts a Int16 value to a 128-bit unsigned integer.
Explicit(Int32 to UInt128)	Explicitly converts a Int32 value to a 128-bit unsigned integer.
Explicit(Int64 to UInt128)	Explicitly converts a Int64 value to a 128-bit unsigned integer.

Explicit(Double to UInt128)	Explicitly converts a Double value to a 128-bit unsigned integer.
Explicit(SByte to UInt128)	Explicitly converts a SByte value to a 128-bit unsigned integer.
Explicit(Single to UInt128)	Explicitly converts a Single value to a 128-bit unsigned integer.
Explicit(UInt128 to Byte)	Explicitly converts a 128-bit unsigned integer to a Byte value.
Explicit(UInt128 to Char)	Explicitly converts a 128-bit unsigned integer to a Char value.
Explicit(IntPtr to UInt128)	Explicitly converts a IntPtr value to a 128-bit unsigned integer.

Explicit(UInt128 to UIntPtr)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit unsigned integer to a UIntPtr value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator UIntPtr (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

UIntPtr

`value` converted to a UIntPtr.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to UInt64)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit unsigned integer to a UInt64 value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator ulong (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

UInt64

`value` converted to a UInt64.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to UInt32)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit unsigned integer to a UInt32 value.

C#

```
[System.CLSCompliant(false)]
public static explicit operator uint (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

UInt32

`value` converted to a UInt32.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to UInt16)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit unsigned integer to a UInt16 value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator ushort (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

UInt16

`value` converted to a UInt16.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Single)

Explicitly converts a 128-bit unsigned integer to a Single value.

```
C#

public static explicit operator float (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Single

`value` converted to a Single.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to SByte)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit unsigned integer to a SByte value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator sbyte (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

SByte

`value` converted to a SByte.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to IntPtr)

Explicitly converts a 128-bit unsigned integer to a IntPtr value.

```
C#
public static explicit operator IntPtr (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

IntPtr

`value` converted to a IntPtr.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Int64)

Explicitly converts a 128-bit unsigned integer to a Int64 value.

```
C#
public static explicit operator long (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Int64

`value` converted to a Int64.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Int32)

Explicitly converts a 128-bit unsigned integer to a Int32 value.

```
C#
public static explicit operator int (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Int32

`value` converted to a Int32.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Int128)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a 128-bit unsigned integer to a Int128 value.

```
C#

[System.CLSCompliant(false)]
public static explicit operator Int128 (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Int128

`value` converted to a Int128.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Half)

Explicitly converts a 128-bit unsigned integer to a Half value.

```
C#
public static explicit operator Half (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Half

`value` converted to a Half.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Int16)

Explicitly converts a 128-bit unsigned integer to a Int16 value.

```
C#
public static explicit operator short (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Int16

`value` converted to a Int16.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Decimal)

Explicitly converts a 128-bit unsigned integer to a Decimal value.

```
C#

public static explicit operator decimal (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Decimal

`value` converted to a Decimal.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Decimal to UInt128)

Explicitly converts a Decimal value to a 128-bit unsigned integer.

```
C#
public static explicit operator UInt128 (decimal value);
```

Parameters

`value` Decimal

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Double)

Explicitly converts a 128-bit unsigned integer to a Double value.

```
C#
public static explicit operator double (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Double

`value` converted to a Double.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int16 to UInt128)

Explicitly converts a Int16 value to a 128-bit unsigned integer.

C#

```
public static explicit operator UInt128 (short value);
```

Parameters

`value` Int16

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int32 to UInt128)

Explicitly converts a Int32 value to a 128-bit unsigned integer.

C#

```
public static explicit operator UInt128 (int value);
```

Parameters

`value` Int32

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Int64 to UInt128)

Explicitly converts a Int64 value to a 128-bit unsigned integer.

C#

```
public static explicit operator UInt128 (long value);
```

Parameters

`value` Int64

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Double to UInt128)

Explicitly converts a Double value to a 128-bit unsigned integer.

C#

```
public static explicit operator UInt128 (double value);
```

Parameters

`value` Double

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(SByte to UInt128)

> Important
>
> This API is not CLS-compliant.

Explicitly converts a SByte value to a 128-bit unsigned integer.

```
C#

[System.CLSCompliant(false)]
public static explicit operator UInt128 (sbyte value);
```

Parameters

`value` SByte

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(Single to UInt128)

Explicitly converts a Single value to a 128-bit unsigned integer.

```
C#

public static explicit operator UInt128 (float value);
```

Parameters

`value` Single

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Byte)

Explicitly converts a 128-bit unsigned integer to a Byte value.

```
C#
public static explicit operator byte (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Byte

`value` converted to a Byte.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(UInt128 to Char)

Explicitly converts a 128-bit unsigned integer to a Char value.

```
C#
public static explicit operator char (UInt128 value);
```

Parameters

`value` UInt128

The value to convert.

Returns

Char

`value` converted to a Char.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Explicit(IntPtr to UInt128)

Explicitly converts a IntPtr value to a 128-bit unsigned integer.

```
C#
public static explicit operator UInt128 (IntPtr value);
```

Parameters

`value` IntPtr

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.GreaterThan(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#
public static bool operator > (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to compare with `right`.

`right` UInt128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.GreaterThanOrEqual(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#
public static bool operator >= (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to compare with `right`.

`right` UInt128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.Implicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Implicit(Byte to UInt128)	Implicitly converts a Byte value to a 128-bit unsigned integer.
Implicit(Char to UInt128)	Implicitly converts a Char value to a 128-bit unsigned integer.
Implicit(UInt16 to UInt128)	Implicitly converts a UInt16 value to a 128-bit unsigned integer.
Implicit(UInt32 to UInt128)	Implicitly converts a UInt32 value to a 128-bit unsigned integer.
Implicit(UInt64 to UInt128)	Implicitly converts a UInt64 value to a 128-bit unsigned integer.
Implicit(UIntPtr to UInt128)	Implicitly converts a UIntPtr value to a 128-bit unsigned integer.

Implicit(Byte to UInt128)

Implicitly converts a Byte value to a 128-bit unsigned integer.

C#

```
public static implicit operator UInt128 (byte value);
```

Parameters

`value` Byte

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(Char to UInt128)

Implicitly converts a Char value to a 128-bit unsigned integer.

C#

```
public static implicit operator UInt128 (char value);
```

Parameters

`value` Char

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UInt16 to UInt128)

Important

This API is not CLS-compliant.

Implicitly converts a UInt16 value to a 128-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator UInt128 (ushort value);
```

Parameters

`value` UInt16

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UInt32 to UInt128)

Important

This API is not CLS-compliant.

Implicitly converts a UInt32 value to a 128-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator UInt128 (uint value);
```

Parameters

`value` UInt32

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UInt64 to UInt128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a UInt64 value to a 128-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator UInt128 (ulong value);
```

Parameters

`value` UInt64

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Implicit(UIntPtr to UInt128)

> Important
>
> This API is not CLS-compliant.

Implicitly converts a UIntPtr value to a 128-bit unsigned integer.

C#

```
[System.CLSCompliant(false)]
public static implicit operator UInt128 (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to convert.

Returns

UInt128

`value` converted to a 128-bit unsigned integer.

Attributes CLSCompliantAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

UInt128.Increment(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
public static UInt128 operator ++ (UInt128 value);
```

Parameters

`value` UInt128

The value to increment.

Returns

UInt128

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.Inequality(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#
public static bool operator != (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to compare with `right`.

`right` UInt128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.LeftShift(UInt128, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

C#

```
public static UInt128 operator << (UInt128 value, int shiftAmount);
```

Parameters

`value` UInt128

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

UInt128

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.LessThan(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#
public static bool operator < (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to compare with `right`.

`right` UInt128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.LessThanOrEqual(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#
public static bool operator <= (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value to compare with `right`.

`right` UInt128

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.Modulus(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#
public static UInt128 operator % (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value which `right` divides.

`right` UInt128

The value which divides `left`.

Returns

UInt128

The modulus or remainder of `left` divided-by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Multiply(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#
public static UInt128 operator * (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value which `right` multiplies.

`right` UInt128

The value which multiplies `left`.

Returns

UInt128

The product of `left` multiplied-by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.OnesComplement(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

C#

```
public static UInt128 operator ~ (UInt128 value);
```

Parameters

`value` UInt128

The value for which to compute the ones-complement.

Returns

UInt128

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.RightShift(UInt128, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#
public static UInt128 operator >> (UInt128 value, int shiftAmount);
```

Parameters

`value` UInt128

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt128

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Remarks

This operation is meant to perform a signed (otherwise known as an arithmetic) right shift on signed types.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.Subtraction(UInt128, UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#
public static UInt128 operator - (UInt128 left, UInt128 right);
```

Parameters

`left` UInt128

The value from which `right` is subtracted.

`right` UInt128

The value which is subtracted from `left`.

Returns

UInt128

The difference of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.UnaryNegation(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
public static UInt128 operator - (UInt128 value);
```

Parameters

`value` UInt128

The value for which to compute the unary negation.

Returns

UInt128

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.UnaryPlus(UInt128) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
public static UInt128 operator + (UInt128 value);
```

Parameters

`value` UInt128

The value for which to compute the unary plus.

Returns

UInt128

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.UnsignedRightShift(UInt128, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

C#

```
public static UInt128 op_UnsignedRightShift (UInt128 value, int
shiftAmount);
```

Parameters

`value` UInt128

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt128

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Remarks

This operation is meant to perform n unsigned (otherwise known as a logical) right shift on all types.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.IBinaryInteger<UInt128>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<UInt128>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumber<UInt128>.CopySign(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
static UInt128 INumber<UInt128>.CopySign (UInt128 value, UInt128 sign);
```

Parameters

`value` UInt128

The value whose magnitude is used in the result.

`sign` UInt128

The value whose sign is used in the result.

Returns

UInt128

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumber<UInt128>.MaxNumber(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

C#

```
static UInt128 INumber<UInt128>.MaxNumber (UInt128 x, UInt128 y);
```

Parameters

x UInt128

The value to compare with `y`.

y UInt128

The value to compare with `x`.

Returns

UInt128

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumber<UInt128>.MinNumber(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

C#

```
static UInt128 INumber<UInt128>.MinNumber (UInt128 x, UInt128 y);
```

Parameters

x UInt128

The value to compare with `y`.

y UInt128

The value to compare with `x`.

Returns

UInt128

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.Abs(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static UInt128 INumberBase<UInt128>.Abs (UInt128 value);
```

Parameters

`value` UInt128

The value for which to get its absolute.

Returns

UInt128

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.IsCanonical(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

C#

```
static bool INumberBase<UInt128>.IsCanonical (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.IsComplexNumber(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

C#

```
static bool INumberBase<UInt128>.IsComplexNumber (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.INumberBase<UInt128>.IsFinite(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<UInt128>.IsFinite (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.INumberBase<UInt128>.IsImaginaryNumber(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<UInt128>.IsImaginaryNumber (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.INumberBase<UInt128>.IsInfinity(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

C#

```
static bool INumberBase<UInt128>.IsInfinity (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.INumberBase<UInt128>.IsInteger(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

C#

```
static bool INumberBase<UInt128>.IsInteger (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.IsNaN(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<UInt128>.IsNaN (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.INumberBase<UInt128>.IsNegative(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<UInt128>.IsNegative (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.IsNormal(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<UInt128>.IsNormal (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.IsPositive(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
static bool INumberBase<UInt128>.IsPositive (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.IsRealNumber(UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

C#

```
static bool INumberBase<UInt128>.IsRealNumber (UInt128 value);
```

Parameters

`value` UInt128

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.MaxMagnitude(UInt128, UInt128) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static UInt128 INumberBase<UInt128>.MaxMagnitude (UInt128 x, UInt128 y);
```

Parameters

x UInt128

The value to compare with `y`.

y UInt128

The value to compare with `x`.

Returns

UInt128

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<UInt128>.TryConvertToChecked<TOther> (UInt128 value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt128

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt128.INumberBase<UInt128>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<UInt128>.TryConvertToSaturating<TOther> (UInt128
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt128

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt128.INumberBase<UInt128>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<UInt128>.TryConvertToTruncating<TOther> (UInt128
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt128

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Remarks

The UInt16 value type represents unsigned integers with values ranging from 0 to 65535.

> **Important**
>
> The **UInt16** type is not CLS-compliant. The CLS-compliant alternative type is **Int32**. **Int16** can be used instead to replace a **UInt16** value that ranges from zero to **Int16.MaxValue**. For more information about CLS compliance, see **Language Independence and Language-Independent Components**.

The UInt16 structure provides methods to compare instances of this type, convert the value of an instance to its string representation, and convert the string representation of a number to an instance of this type.

For information about how format specification codes control the string representation of value types, see Formatting Types.

Fields

Expand table

MaxValue	Represents the largest possible value of UInt16. This field is constant.
MinValue	Represents the smallest possible value of UInt16. This field is constant.

Methods

Expand table

Clamp(UInt16, UInt16, UInt16)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.

CompareTo(UInt16)	Compares this instance to a specified 16-bit unsigned integer and returns an indication of their relative values.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(UInt16, UInt16)	Computes the quotient and remainder of two values.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UInt16)	Returns a value indicating whether this instance is equal to a specified UInt16 value.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type UInt16.
IsEvenInteger(UInt16)	Determines if a value represents an even integral number.
IsOddInteger(UInt16)	Determines if a value represents an odd integral number.
IsPow2(UInt16)	Determines if a value is a power of two.
LeadingZeroCount(UInt16)	Computes the number of leading zeros in a value.
Log2(UInt16)	Computes the log2 of a value.
Max(UInt16, UInt16)	Compares two values to compute which is greater.
Min(UInt16, UInt16)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit unsigned

	integer equivalent.
Parse(String)	Converts the string representation of a number to its 16-bit unsigned integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 16-bit unsigned integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 16-bit unsigned integer equivalent. This method is not CLS-compliant. The CLS-compliant alternative is Parse(String, NumberStyles).
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent.
PopCount(UInt16)	Computes the number of bits that are set in a value.
RotateLeft(UInt16, Int32)	Rotates a value left by a given amount.
RotateRight(UInt16, Int32)	Rotates a value right by a given amount.
Sign(UInt16)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
TrailingZeroCount(UInt16)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current unsigned short number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>,	Tries to parse a span of UTF-8 characters into a value.

IFormatProvider, UInt16)	
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, UInt16)	Tries to convert a UTF-8 character span containing the string representation of a number to its 16-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt16)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt16)	Tries to convert the span representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, UInt16)	Tries to convert the span representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, UInt16)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, UInt16)	Tries to convert the string representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, UInt16)	Tries to convert the string representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<UInt16,UInt16,UInt16>.Addition(UInt16, UInt16)	Adds two values together to compute their sum.
IAdditionOperators<UInt16,UInt16,UInt16>.CheckedAddition(UInt16, UInt16)	Adds two values together to compute their sum.
IAdditiveIdentity<UInt16,UInt16>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<UInt16>.GetByteCount()	Gets the number of bytes that will be written as part of

	TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<UInt16>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<UInt16>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, UInt16)	
IBinaryInteger<UInt16>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, UInt16)	
IBinaryInteger<UInt16>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<UInt16>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<UInt16>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<UInt16,UInt16,UInt16>.BitwiseAnd(UInt16, UInt16)	Computes the bitwise-and of two values.
IBitwiseOperators<UInt16,UInt16,UInt16>.BitwiseOr(UInt16, UInt16)	Computes the bitwise-or of two values.
IBitwiseOperators<UInt16,UInt16,UInt16>.ExclusiveOr(UInt16, UInt16)	Computes the exclusive-or of two values.
IBitwiseOperators<UInt16,UInt16,UInt16>.OnesComplement(UInt16)	Computes the ones-complement representation of a given value.
IComparisonOperators<UInt16,UInt16,Boolean>.GreaterThan(UInt16, UInt16)	Compares two values to determine which is greater.
IComparisonOperators<UInt16,UInt16,Boolean>.GreaterThanOrEqual(UInt16, UInt16)	Compares two values to determine which is greater or equal.
IComparisonOperators<UInt16,UInt16,Boolean>.LessThan(UInt16, UInt16)	Compares two values to determine which is less.
IComparisonOperators<UInt16,UInt16,Boolean>.LessThanOrEqual(UInt16, UInt16)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member,

	see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<UInt16>.CheckedDecrement(UInt16)	Decrements a value.
IDecrementOperators<UInt16>.Decrement(UInt16)	Decrements a value.
IDivisionOperators<UInt16,UInt16,UInt16>.Division(UInt16, UInt16)	Divides one value by another to compute their quotient.
IEqualityOperators<UInt16,UInt16,Boolean>.Equality(UInt16, UInt16)	Compares two values to determine equality.
IEqualityOperators<UInt16,UInt16,Boolean>.Inequality(UInt16, UInt16)	Compares two values to determine inequality.

IIncrementOperators<UInt16>.CheckedIncrement(UInt16)	Increments a value.
IIncrementOperators<UInt16>.Increment(UInt16)	Increments a value.
IMinMaxValue<UInt16>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<UInt16>.MinValue	Gets the minimum value of the current type.
IModulus Operators<UInt16,UInt16,UInt16>.Modulus(UInt16, UInt16)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<UInt16,UInt16>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiplyOperators<UInt16,UInt16,UInt16>.Checked Multiply(UInt16, UInt16)	Multiplies two values together to compute their product.
IMultiplyOperators<UInt16,UInt16,UInt16>.Multiply(UInt16, UInt16)	Multiplies two values together to compute their product.
INumber<UInt16>.CopySign(UInt16, UInt16)	Copies the sign of a value to the sign of another value.
INumber<UInt16>.MaxNumber(UInt16, UInt16)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<UInt16>.MinNumber(UInt16, UInt16)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<UInt16>.Abs(UInt16)	Computes the absolute of a value.
INumberBase<UInt16>.IsCanonical(UInt16)	Determines if a value is in its canonical representation.
INumberBase<UInt16>.IsComplexNumber(UInt16)	Determines if a value represents a complex number.
INumberBase<UInt16>.IsFinite(UInt16)	Determines if a value is finite.
INumberBase<UInt16>.IsImaginaryNumber(UInt16)	Determines if a value represents a pure imaginary number.
INumberBase<UInt16>.IsInfinity(UInt16)	Determines if a value is infinite.
INumberBase<UInt16>.IsInteger(UInt16)	Determines if a value represents an integral number.

INumberBase<UInt16>.IsNaN(UInt16)	Determines if a value is NaN.
INumberBase<UInt16>.IsNegative(UInt16)	Determines if a value is negative.
INumberBase<UInt16>.IsNegativeInfinity(UInt16)	Determines if a value is negative infinity.
INumberBase<UInt16>.IsNormal(UInt16)	Determines if a value is normal.
INumberBase<UInt16>.IsPositive(UInt16)	Determines if a value is positive.
INumberBase<UInt16>.IsPositiveInfinity(UInt16)	Determines if a value is positive infinity.
INumberBase<UInt16>.IsRealNumber(UInt16)	Determines if a value represents a real number.
INumberBase<UInt16>.IsSubnormal(UInt16)	Determines if a value is subnormal.
INumberBase<UInt16>.IsZero(UInt16)	Determines if a value is zero.
INumberBase<UInt16>.MaxMagnitude(UInt16, UInt16)	Compares two values to compute which is greater.
INumberBase<UInt16>.MaxMagnitudeNumber(UInt16, UInt16)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt16>.MinMagnitude(UInt16, UInt16)	Compares two values to compute which is lesser.
INumberBase<UInt16>.MinMagnitudeNumber(UInt16, UInt16)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt16>.One	Gets the value `1` for the type.
INumberBase<UInt16>.Radix	Gets the radix, or base, for the type.
INumberBase<UInt16>.TryConvertFromChecked<TOther>(TOther, UInt16)	
INumberBase<UInt16>.TryConvertFromSaturating<TOther>(TOther, UInt16)	
INumberBase<UInt16>.TryConvertFromTruncating<TOther>(TOther, UInt16)	
INumberBase<UInt16>.TryConvertToChecked<TOther>(UInt16, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the

	representable range of the current type.
INumberBase<UInt16>.TryConvertToSaturating<TOther>(UInt16, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<UInt16>.TryConvertToTruncating<TOther>(UInt16, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<UInt16>.Zero	Gets the value `0` for the type.
IShiftOperators<UInt16,Int32,UInt16>.LeftShift(UInt16, Int32)	Shifts a value left by a given amount.
IShiftOperators<UInt16,Int32,UInt16>.RightShift(UInt16, Int32)	Shifts a value right by a given amount.
IShiftOperators<UInt16,Int32,UInt16>.UnsignedRightShift(UInt16, Int32)	Shifts a value right by a given amount.
ISubtractionOperators<UInt16,UInt16,UInt16>.CheckedSubtraction(UInt16, UInt16)	Subtracts two values to compute their difference.
ISubtractionOperators<UInt16,UInt16,UInt16>.Subtraction(UInt16, UInt16)	Subtracts two values to compute their difference.
IUnaryNegationOperators<UInt16,UInt16>.CheckedUnaryNegation(UInt16)	Computes the checked unary negation of a value.
IUnaryNegationOperators<UInt16,UInt16>.UnaryNegation(UInt16)	Computes the unary negation of a value.
IUnaryPlusOperators<UInt16,UInt16>.UnaryPlus(UInt16)	Computes the unary plus of a value.

UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

UInt16.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of UInt16. This field is constant.

C#

```
public const ushort MaxValue = 65535;
```

Field Value

***Value* = 65535**

UInt16

Examples

The following example uses the UInt16.MaxValue and UInt16.MinValue properties to ensure that an Int32 value is in the range of the UInt16 type before converting it to a UInt16 value. This prevents the conversion operation from throwing an OverflowException if the integer value is not in the range of the UInt16 type.

C#

```
int integerValue = 1216;
ushort uIntegerValue;

if (integerValue >= ushort.MinValue & integerValue <= ushort.MaxValue)
{
   uIntegerValue = (ushort) integerValue;
   Console.WriteLine(uIntegerValue);
}
else
{
   Console.WriteLine("Unable to convert {0} to a UInt16t.", integerValue);
}
```

Remarks

The value of this constant is 65535; that is, hexadecimal 0xFFFF.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt16.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of UInt16. This field is constant.

C#

```
public const ushort MinValue = 0;
```

Field Value

Value* = *0

UInt16

Examples

The following example uses the MinValue and MaxValue properties to ensure that an Int32 value is in the range of the UInt16 type before converting it to a UInt16 value. This prevents the conversion operation from throwing an OverflowException if the integer value is not in the range of the UInt16 type.

C#

```
int integerValue = 1216;
ushort uIntegerValue;

if (integerValue >= ushort.MinValue & integerValue <= ushort.MaxValue)
{
   uIntegerValue = (ushort) integerValue;
   Console.WriteLine(uIntegerValue);
}
else
{
   Console.WriteLine("Unable to convert {0} to a UInt16t.", integerValue);
}
```

Remarks

The value of this constant is 0.

UInt16.Clamp(UInt16, UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static ushort Clamp (ushort value, ushort min, ushort max);
```

Parameters

`value` UInt16

The value to clamp.

`min` UInt16

The inclusive minimum to which `value` should clamp.

`max` UInt16

The inclusive maximum to which `value` should clamp.

Returns

UInt16

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or UInt16 and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CompareTo(UInt16)	Compares this instance to a specified 16-bit unsigned integer and returns an indication of their relative values.

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

value Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a UInt16.

Examples

The following example demonstrates the CompareTo method.

C#

```
public class Temperature : IComparable {
    /// <summary>
    /// IComparable.CompareTo implementation.
    /// </summary>
    public int CompareTo(object obj) {
        if(obj is Temperature) {
            Temperature temp = (Temperature) obj;

            return m_value.CompareTo(temp.m_value);
        }

        throw new ArgumentException("object is not a Temperature");
    }

    // The value holder
    protected ushort m_value;

    public ushort Value {
        get {
            return m_value;
        }
```

```
        set {
            m_value = value;
        }
    }
}
```

Remarks

Any instance of UInt16, regardless of its value, is considered greater than `null`.

`value` must be `null` or an instance of UInt16; otherwise, an exception is thrown.

CompareTo(UInt16)

Compares this instance to a specified 16-bit unsigned integer and returns an indication of their relative values.

C#

```
public int CompareTo (ushort value);
```

Parameters

`value` UInt16

An unsigned integer to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
```

```
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
```

```
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the UInt16.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

UInt16.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static ushort CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt16

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static ushort CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

TOther

The type of `value`.

Parameters

value TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt16

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static ushort CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt16

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.DivRem(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

C#

```
public static (ushort Quotient, ushort Remainder) DivRem (ushort left,
ushort right);
```

Parameters

`left` UInt16

The value which `right` divides.

`right` UInt16

The value which divides `left`.

Returns

ValueTuple<UInt16,UInt16>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or UInt16.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UInt16)	Returns a value indicating whether this instance is equal to a specified UInt16 value.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare to this instance.

Returns

Boolean

`true` if `obj` is an instance of UInt16 and equals the value of this instance; otherwise, `false`.

Examples

The following example demonstrates the Equals method.

C#

```
UInt16 myVariable1 = 10;
UInt16 myVariable2 = 10;

//Display the declaring type.
Console.WriteLine("\nType of 'myVariable1' is '{0}' and" +
     " value is :{1}", myVariable1.GetType(), myVariable1);
Console.WriteLine("Type of 'myVariable2' is '{0}' and" +
     " value is :{1}", myVariable2.GetType(), myVariable2);

// Compare 'myVariable1' instance with 'myVariable2' Object.
if (myVariable1.Equals(myVariable2))
    Console.WriteLine("\nStructures 'myVariable1' and " +
          "'myVariable2' are equal");
else
    Console.WriteLine("\nStructures 'myVariable1' and " +
          "'myVariable2' are not equal");
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(UInt16) method overloads. If an implicit conversion between the `obj` argument and a UInt16 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(UInt16) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a UInt16 value. The following example illustrates the difference in behavior between the two method overloads. In the case of a Byte value, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(UInt16) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static ushort value = 112;

   public static void Main()
   {
      byte byte1= 112;
```

```
        Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
        TestObjectForEquality(byte1);

        short short1 = 112;
        Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
        TestObjectForEquality(short1);

        int int1 = 112;
        Console.WriteLine("value = int1: {0,19}", value.Equals(int1));
        TestObjectForEquality(int1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (UInt16) = 112 (Byte): False
//
//       value = short1:             False
//       112 (UInt16) = 112 (Int16): False
//
//       value = int1:               False
//       112 (UInt16) = 112 (Int32): False
//
//       value = sbyte1:             False
//       112 (UInt16) = 112 (SByte): False
//
//       value = dec1:                 False
//       112 (UInt16) = 112 (Decimal): False
//
//       value = dbl1:                 False
//       112 (UInt16) = 112 (Double): False
```

Equals(UInt16)

Returns a value indicating whether this instance is equal to a specified UInt16 value.

C#

```
public bool Equals (ushort obj);
```

Parameters

`obj` UInt16

A 16-bit unsigned integer to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(UInt16) method overloads. If an implicit conversion between the `obj` argument and a UInt16 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(UInt16) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a UInt16 value. The following example illustrates the difference in behavior between the two method overloads. In the case of a Byte value, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(UInt16) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static ushort value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,19}", value.Equals(int1));
      TestObjectForEquality(int1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);

      decimal dec1 = 112m;
      Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
      TestObjectForEquality(dec1);

      double dbl1 = 112;
      Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
      TestObjectForEquality(dbl1);
   }

   private static void TestObjectForEquality(Object obj)
   {
```

```
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (UInt16) = 112 (Byte): False
//
//       value = short1:             False
//       112 (UInt16) = 112 (Int16): False
//
//       value = int1:               False
//       112 (UInt16) = 112 (Int32): False
//
//       value = sbyte1:             False
//       112 (UInt16) = 112 (SByte): False
//
//       value = dec1:                 False
//       112 (UInt16) = 112 (Decimal): False
//
//       value = dbl1:                False
//       112 (UInt16) = 112 (Double): False
```

UInt16.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt16.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type UInt16.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, UInt16.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UInt16.IsEvenInteger(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.IsOddInteger(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.IsPow2(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.LeadingZeroCount(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static ushort LeadingZeroCount (ushort value);
```

Parameters

`value` UInt16

The value whose leading zeroes are to be counted.

Returns

UInt16

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.Log2(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static ushort Log2 (ushort value);
```

Parameters

`value` UInt16

The value whose log2 is to be computed.

Returns

UInt16

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.Max(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static ushort Max (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.Min(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static ushort Min (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 16-bit unsigned integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 16-bit unsigned integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 16-bit unsigned integer equivalent. This method is not CLS-compliant. The CLS-compliant alternative is Parse(String, NumberStyles).
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String)	Converts the string representation of a number to its 16-bit unsigned integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int32.Parse(String)**

Converts the string representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent.

C#

```
public static ushort Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicate the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt16

A 16-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number that is less than UInt16.MinValue or greater than UInt16.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example uses the Parse(String, NumberStyles, IFormatProvider) method to convert various string representations of numbers to 16-bit unsigned integer values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] cultureNames = { "en-US", "fr-FR" };
      NumberStyles[] styles= { NumberStyles.Integer,
                               NumberStyles.Integer |
NumberStyles.AllowDecimalPoint };
      string[] values = { "1702", "+1702.0", "+1702,0", "-1032.00",
                          "-1032,00", "1045.1", "1045,1" };

      // Parse strings using each culture
      foreach (string cultureName in cultureNames)
      {
```

```
         CultureInfo ci = new CultureInfo(cultureName);
         Console.WriteLine("Parsing strings using the {0} culture",
                           ci.DisplayName);
         // Use each style.
         foreach (NumberStyles style in styles)
         {
            Console.WriteLine("   Style: {0}", style.ToString());
            // Parse each numeric string.
            foreach (string value in values)
            {
               try {
                  Console.WriteLine("      Converted '{0}' to {1}.",
value,
                                    UInt16.Parse(value, style, ci));
               }
               catch (FormatException) {
                  Console.WriteLine("      Unable to parse '{0}'.",
value);
               }
               catch (OverflowException) {
                  Console.WriteLine("      '{0}' is out of range of the
UInt16 type.",
                                    value);
               }
            }
         }
      }
   }
}
// The example displays the following output:
//       Parsing strings using the English (United States) culture
//          Style: Integer
//             Converted '1702' to 1702.
//             Unable to parse '+1702.0'.
//             Unable to parse '+1702,0'.
//             Unable to parse '-1032.00'.
//             Unable to parse '-1032,00'.
//             Unable to parse '1045.1'.
//             Unable to parse '1045,1'.
//          Style: Integer, AllowDecimalPoint
//             Converted '1702' to 1702.
//             Converted '+1702.0' to 1702.
//             Unable to parse '+1702,0'.
//             '-1032.00' is out of range of the UInt16 type.
//             Unable to parse '-1032,00'.
//             '1045.1' is out of range of the UInt16 type.
//             Unable to parse '1045,1'.
//       Parsing strings using the French (France) culture
//          Style: Integer
//             Converted '1702' to 1702.
//             Unable to parse '+1702.0'.
//             Unable to parse '+1702,0'.
//             Unable to parse '-1032.00'.
//             Unable to parse '-1032,00'.
//             Unable to parse '1045.1'.
```

```
//             Unable to parse '1045,1'.
//          Style: Integer, AllowDecimalPoint
//             Converted '1702' to 1702.
//             Unable to parse '+1702.0'.
//             Converted '+1702,0' to 1702.
//             Unable to parse '-1032.00'.
//             '-1032,00' is out of range of the UInt16 type.
//             Unable to parse '1045.1'.
//             '1045,1' is out of range of the UInt16 type.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive or negative sign symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Elements in square brackets ([and]) are optional. If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object that is returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. (The method throws an OverflowException if `s` includes a negative sign and represents a non-zero number.) The sign can appear

Element	Description
	at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0-9 if `style` includes the NumberStyles.AllowExponent flag, or one or more occurrences of the digit 0 if it does not. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
NumberStyles.None	Decimal digits only.

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, if style does not include the NumberStyles.AllowExponent flag, *fractional_digits* must consist of only one or more 0 digits; otherwise, an OverflowException is thrown.
NumberStyles.AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign before *digits*.
NumberStyles.AllowTrailingSign	A sign after *digits*.
NumberStyles.AllowParentheses	Parentheses before and after *digits* to indicate a negative value.
NumberStyles.AllowThousands	The group separator (,) element.
NumberStyles.AllowCurrencySymbol	The currency ($) element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. Valid hexadecimal digits are 0 through 9, a through f, and A through F. A prefix, such as "0x", is not supported and causes the parse operation to fail. The only other flags that can be combined with NumberStyles.AllowHexSpecifier are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

> **Note**
>
> If the `s` parameter is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the parse operation to throw an exception.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

UWP	10.0

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the span representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent.

C#

```
public static ushort Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicate the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt16

A 16-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static ushort Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt16

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int32.Parse(String)**

Converts the string representation of a number in a specified culture-specific format to its 16-bit unsigned integer equivalent.

C#

```
public static ushort Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that represents the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt16

A 16-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example instantiates a custom culture that uses two plus signs (++) as its positive sign. It then calls the Parse(String, IFormatProvider) method to parse an array of strings by using CultureInfo objects that represent both this custom culture and the invariant culture.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define a custom culture that uses "++" as a positive sign.
      CultureInfo ci = new CultureInfo("");
      ci.NumberFormat.PositiveSign = "++";
      // Create an array of cultures.
      CultureInfo[] cultures = { ci, CultureInfo.InvariantCulture };
      // Create an array of strings to parse.
      string[] values = { "++1403", "-0", "+0", "+16034",
                          Int16.MinValue.ToString(), "14.0", "18012" };
      // Parse the strings using each culture.
      foreach (CultureInfo culture in cultures)
      {
         Console.WriteLine("Parsing with the '{0}' culture.",
culture.Name);
         foreach (string value in values)
         {
            try {
               ushort number = UInt16.Parse(value, culture);
               Console.WriteLine("   Converted '{0}' to {1}.", value,
number);
            }
            catch (FormatException) {
               Console.WriteLine("   The format of '{0}' is invalid.",
value);
            }
            catch (OverflowException) {
               Console.WriteLine("   '{0}' is outside the range of a
UInt16 value.", value);
            }
         }
      }
   }
}
```

```
// The example displays the following output:
//       Parsing with the  culture.
//          Converted '++1403' to 1403.
//          Converted '-0' to 0.
//          The format of '+0' is invalid.
//          The format of '+16034' is invalid.
//          '-32768' is outside the range of a UInt16 value.
//          The format of '14.0' is invalid.
//          Converted '18012' to 18012.
//       Parsing with the '' culture.
//          The format of '++1403' is invalid.
//          Converted '-0' to 0.
//          Converted '+0' to 0.
//          Converted '+16034' to 16034.
//          '-32768' is outside the range of a UInt16 value.
//          The format of '14.0' is invalid.
//          Converted '18012' to 18012.
```

Remarks

The `s` parameter contains a number of the form:

[*ws*][*sign*]*digits*[*ws*]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign, or a negative sign if `s` represents the value zero.
digits	A sequence of digits ranging from 0 to 9.

The s parameter is interpreted using the NumberStyles.Integer style. In addition to the byte value's decimal digits, only leading and trailing spaces along with a leading sign is allowed. (If the negative sign is present, `s` must represent a value of zero or the method throws an OverflowException.) To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific

information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo for the current culture is used.

UWP	10.0

Parse(String, NumberStyles)

> Important
>
> This API is not CLS-compliant.

Converts the string representation of a number in a specified style to its 16-bit unsigned integer equivalent.

This method is not CLS-compliant. The CLS-compliant alternative is Parse(String, NumberStyles).

```
C#

public static ushort Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

s String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

style NumberStyles

A bitwise combination of the enumeration values that specify the permitted format of `s`. A typical value to specify is Integer.

Returns

UInt16

A 16-bit unsigned integer equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number less than UInt16.MinValue or greater than UInt16.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example tries to parse each element in a string array by using a number of NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] values = { " 214 ", "1,064", "(0)", "1241+", " + 214 ", "
+214 ", "2153.0", "1e03", "1300.0e-2" };
      NumberStyles whitespace =  NumberStyles.AllowLeadingWhite |
NumberStyles.AllowTrailingWhite;
      NumberStyles[] styles = { NumberStyles.None, whitespace,
                                NumberStyles.AllowLeadingSign |
NumberStyles.AllowTrailingSign | whitespace,
                                NumberStyles.AllowThousands |
NumberStyles.AllowCurrencySymbol,
                                NumberStyles.AllowExponent |
NumberStyles.AllowDecimalPoint };

      // Attempt to convert each number using each style combination.
      foreach (string value in values)
      {
         Console.WriteLine("Attempting to convert '{0}':", value);
         foreach (NumberStyles style in styles)
         {
            try {
               ushort number = UInt16.Parse(value, style);
               Console.WriteLine("   {0}: {1}", style, number);
            }
            catch (FormatException) {
               Console.WriteLine("   {0}: Bad Format", style);
            }
         }
         Console.WriteLine();
      }
   }
}
```

```
// The example display the following output:
//    Attempting to convert ' 214 ':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: 214
//       Integer, AllowTrailingSign: 214
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '1,064':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: 1064
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '(0)':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '1241+':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: 1241
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert ' + 214 ':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert ' +214 ':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: 214
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '2153.0':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: 2153
//
//    Attempting to convert '1e03':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
```

```
//       AllowDecimalPoint, AllowExponent: 1000
//
//    Attempting to convert '1300.0e-2':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: 13
```

Remarks

The `style` parameter defines the style elements (such as white space, the positive or negative sign symbol, the group separator symbol, or the decimal point symbol) that are allowed in the `s` parameter for the parse operation to succeed. `style` must be a combination of bit flags from the NumberStyles enumeration. The `style` parameter makes this method overload useful when `s` contains the string representation of a hexadecimal value, when the number system (decimal or hexadecimal) represented by `s` is known only at run time, or when you want to disallow white space or a sign symbol in `s`.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Elements in square brackets ([and]) are optional. If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may contain the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current

Element	Description
	culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag. However, the negative sign symbol can be used only with zero; otherwise, the method throws an OverflowException.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.
,	A culture-specific group separator symbol. The current culture's group separator can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, a FormatException is thrown.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the UInt16 type. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

`NumberStyles` value	Elements permitted in `s` in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
AllowLeadingWhite	The *ws* element at the start of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the start of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `s`, *sign* at the start of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, group separator (,), and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

Unlike the other NumberStyles values, which allow for, but do not require, the presence of particular style elements in `s`, the NumberStyles.AllowHexSpecifier style value means that the individual numeric characters in `s` are always interpreted as hexadecimal characters. Valid hexadecimal characters are 0-9, A-F, and a-f. A prefix, such as "0x", is not supported and causes the parse operation to fail. The only other flags that can be combined with the `style` parameter are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

Note

If `s` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To specify the culture whose formatting information is used for the parse operation, call the Parse(String, NumberStyles, IFormatProvider) overload.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static ushort Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt16

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static ushort Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt16

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int32.Parse(String)**

Converts the string representation of a number to its 16-bit unsigned integer equivalent.

C#

```
public static ushort Parse (string s);
```

Parameters

s String

A string that represents the number to convert.

Returns

UInt16

A 16-bit unsigned integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than UInt16.MinValue or greater than UInt16.MaxValue.

Examples

The following example calls the Parse(String) method to convert each element in a string array to an unsigned 16-bit integer.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string[] values = { "-0", "17", "-12", "185", "66012", "+0",
                          "", null, "16.1", "28.0", "1,034" };
      foreach (string value in values)
      {
         try {
            ushort number = UInt16.Parse(value);
            Console.WriteLine("'{0}' --> {1}", value, number);
         }
         catch (FormatException) {
            Console.WriteLine("'{0}' --> Bad Format", value);
         }
         catch (OverflowException) {
            Console.WriteLine("'{0}' --> OverflowException", value);
         }
         catch (ArgumentNullException) {
            Console.WriteLine("'{0}' --> Null", value);
         }
      }
   }
}
// The example displays the following output:
//       '-0' --> 0
```

```
//       '17' --> 17
//       '-12' --> OverflowException
//       '185' --> 185
//       '66012' --> OverflowException
//       '+0' --> 0
//       '' --> Bad Format
//       '' --> Null
//       '16.1' --> Bad Format
//       '28.0' --> Bad Format
//       '1,034' --> Bad Format
```

Remarks

The `s` parameter should be the string representation of a number in the following form.

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture. However, the negative sign symbol can be used only with zero; otherwise, the method throws an OverflowException.
digits	A sequence of digits ranging from 0 to 9. Any leading zeros are ignored.

> **Note**
>
> The string specified by the `s` parameter is interpreted by using the **NumberStyles.Integer** style. It cannot contain any group separators or decimal separator, and it cannot have a decimal portion.

The `s` parameter is parsed by using the formatting information in a System.Globalization.NumberFormatInfo object that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse a string by using the formatting information of a specific culture, use the Parse(String, IFormatProvider) method.

UInt16.PopCount(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static ushort PopCount (ushort value);
```

Parameters

`value` UInt16

The value whose set bits are to be counted.

Returns

UInt16

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.RotateLeft(UInt16, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

C#

```
public static ushort RotateLeft (ushort value, int rotateAmount);
```

Parameters

`value` UInt16

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

UInt16

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.RotateRight(UInt16, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

```
C#
public static ushort RotateRight (ushort value, int rotateAmount);
```

Parameters

`value` UInt16

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

UInt16

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.Sign(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (ushort value);
```

Parameters

`value` UInt16

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString()	Converts the numeric value of this instance to its equivalent string representation.

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance, which consists of a sequence of digits ranging from 0 to 9, without a sign or leading zeros.

Implements

ToString(IFormatProvider)

Examples

The following example formats a 16-bit signed integer value by using several format providers, including one for the invariant culture. The output from the example illustrates that the formatted string returned by the ToString(IFormatProvider) method is the same regardless of the format provider.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define an array of CultureInfo objects.
      CultureInfo[] ci = { new CultureInfo("en-US"),
                           new CultureInfo("fr-FR"),
                           CultureInfo.InvariantCulture };
      UInt16 value = 18924;
      Console.WriteLine("  {0,12}   {1,12}   {2,12}",
                        GetName(ci[0]), GetName(ci[1]), GetName(ci[2]));
      Console.WriteLine("  {0,12}   {1,12}   {2,12}",
                        value.ToString(ci[0]), value.ToString(ci[1]),
value.ToString(ci[2]));
   }

   private static string GetName(CultureInfo ci)
   {
      if (ci.Equals(CultureInfo.InvariantCulture))
         return "Invariant";
      else
         return ci.Name;
   }
}
```

```
// The example displays the following output:
//          en-US          fr-FR      Invariant
//          18924          18924          18924
```

Remarks

The ToString(IFormatProvider) method formats a UInt16 value in the default ("G", or general) format by using the NumberFormatInfo object of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific formatting information. However, none of the properties of the NumberFormatInfo are used when formatting with the general numeric format specifier ("G").

Product	Versions
UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

The `format` parameter is invalid.

Examples

The following example displays a 16-bit unsigned integer value by using each standard format string and some custom format strings.

```
C#

using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
```

```
        ushort value = 21708;
        string[] specifiers = { "G", "C", "D3", "E2", "e3", "F",
                                "N", "P", "X", "000000.0", "#.0",
                                "00000000;(0);**Zero**" };

        foreach (string specifier in specifiers)
           Console.WriteLine("{0}: {1}", specifier,
value.ToString(specifier));
    }
}
// The example displays the following output:
//       G: 21708
//       C: $21,708.00
//       D3: 21708
//       E2: 2.17E+004
//       e3: 2.171e+004
//       F: 21708.00
//       N: 21,708.00
//       P: 2,170,800.00 %
//       X: 54CC
//       000000.0: 021708.0
//       #.0: 21708.0
//       00000000;(0);**Zero**: 00021708
```

Remarks

The ToString(String) method formats a UInt16 value in a specified format by using a NumberFormatInfo object that represents the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be any valid standard numeric format specifier, or any combination of custom numeric format specifiers. If `format` is equal to String.Empty or is `null`, the return value of the current UInt16 object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

The format of the returned string is determined by the NumberFormatInfo object for the current culture. Depending on the `format` parameter, this object controls symbols such as the group separator and the decimal point symbol in the output string. To provide formatting information for cultures other than the current culture, call the ToString(String, IFormatProvider) overload.

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

```
C#
```

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance, as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` is invalid.

Examples

The following example displays a 16-bit unsigned integer value by using the standard numeric format specifiers and a number of specific CultureInfo objects.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define cultures whose formatting conventions are to be used.
      CultureInfo[] cultures = { CultureInfo.CreateSpecificCulture("en-
US"),
```

```
                                    CultureInfo.CreateSpecificCulture("fr-
FR"),
                                    CultureInfo.CreateSpecificCulture("es-
ES") };
      string[] specifiers = {"G", "C", "D4", "E2", "F", "N", "P", "X2"};
      ushort value = 22042;

      foreach (string specifier in specifiers)
      {
         foreach (CultureInfo culture in cultures)
            Console.WriteLine("{0,2} format using {1} culture: {2, 16}",
                              specifier, culture.Name,
                              value.ToString(specifier, culture));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//        G format using en-US culture:            22042
//        G format using fr-FR culture:            22042
//        G format using es-ES culture:            22042
//
//        C format using en-US culture:       $22,042.00
//        C format using fr-FR culture:      22 042,00 €
//        C format using es-ES culture:      22.042,00 €
//
//       D4 format using en-US culture:            22042
//       D4 format using fr-FR culture:            22042
//       D4 format using es-ES culture:            22042
//
//       E2 format using en-US culture:        2.20E+004
//       E2 format using fr-FR culture:        2,20E+004
//       E2 format using es-ES culture:        2,20E+004
//
//        F format using en-US culture:         22042.00
//        F format using fr-FR culture:         22042,00
//        F format using es-ES culture:         22042,00
//
//        N format using en-US culture:        22,042.00
//        N format using fr-FR culture:        22 042,00
//        N format using es-ES culture:        22.042,00
//
//        P format using en-US culture:   2,204,200.00 %
//        P format using fr-FR culture:   2 204 200,00 %
//        P format using es-ES culture:   2.204.200,00 %
//
//       X2 format using en-US culture:             561A
//       X2 format using fr-FR culture:             561A
//       X2 format using es-ES culture:             561A
```

Remarks

The ToString(String, IFormatProvider) method formats a UInt16 value in a specified format by using the NumberFormatInfo object of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be any valid Standard Numeric Format Strings, or any combination of Custom Numeric Format Strings. If `format` is equal to String.Empty or is `null`, the return value of the current UInt16 object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string returned by this method. When the ToString(String, IFormatProvider) method is invoked, it calls the `provider` parameter's IFormatProvider.GetFormat method and passes it a Type object that represents the NumberFormatInfo type. The GetFormat method then returns the NumberFormatInfo object that provides information for formatting the current UInt16 value, such as the group separator symbol or the decimal point symbol. There are three ways to use the `provider` parameter to supply formatting information to the ToString(String, IFormatProvider) method:

- You can pass a CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.

- You can pass the actual NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- You can pass a custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the formatting of the returned string is based on the NumberFormatInfo object of the current culture.

UWP	10.0

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, which consists of a sequence of digits ranging from 0 to 9, without a sign or leading zeros.

Examples

The following example displays a UInt16 value by using the default ToString() method. It also displays the string representations of the UInt16 value that results from using some standard format specifiers. The examples are displayed using the formatting conventions of the en-US culture.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      ushort value = 16324;
      // Display value using default ToString method.
      Console.WriteLine(value.ToString());
      Console.WriteLine();

      // Define an array of format specifiers.
      string[] formats = { "G", "C", "D", "F", "N", "X" };
      // Display value using the standard format specifiers.
      foreach (string format in formats)
         Console.WriteLine("{0} format specifier: {1,12}",
                           format, value.ToString(format));
   }
}
// The example displays the following output:
//       16324
//
//       G format specifier:        16324
//       C format specifier:   $16,324.00
//       D format specifier:        16324
//       F format specifier:     16324.00
//       N format specifier:    16,324.00
//       X format specifier:         3FC4
```

Remarks

The ToString() method formats a UInt16 value in the default ("G", or general) format by using the NumberFormatInfo object of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

UInt16.TrailingZeroCount(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static ushort TrailingZeroCount (ushort value);
```

Parameters

`value` UInt16

The value whose trailing zeroes are to be counted.

Returns

UInt16

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current unsigned short number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current unsigned short number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

UInt16.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, UInt16)	Tries to convert the span representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, UInt16)	Tries to convert the string representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt16)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, UInt16)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt16)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, UInt16)	Tries to convert a UTF-8 character span containing the string representation of a number to its 16-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt16)	Tries to convert the span representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(String, NumberStyles, IFormatProvider, UInt16)	Tries to convert the string representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt16)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out ushort result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt16

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, UInt16)

> Important
>
> This API is not CLS-compliant.

Tries to convert the span representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out ushort result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters representing the number to convert.

`result` UInt16

When this method returns, contains the 16-bit unsigned integer value that is equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in the correct format. , or represents a number less than UInt16.MinValue or greater than UInt16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, UInt16)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int32.TryParse(String, Int32)**

Tries to convert the string representation of a number to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (string? s, out ushort result);
```

Parameters

`s` String

A string that represents the number to convert.

`result` UInt16

When this method returns, contains the 16-bit unsigned integer value that is equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in the correct format, or represents a number less than UInt16.MinValue or greater than UInt16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParse(String, UInt16) method once for each element in a string array.

```
C#
```

```
string[] numericStrings = { "1293.8", "+1671.7", "28347.",
                            "   33113684  ", "(0)", "-0", "-1",
                            "+1293617", "18-", "119870", "31,024",
                            "  3127094 ", "00700000" };
uint number;
foreach (string numericString in numericStrings)
{
   if (UInt32.TryParse(numericString, out number))
      Console.WriteLine("Converted '{0}' to {1}.", numericString,
number);
   else
      Console.WriteLine("Cannot convert '{0}' to a UInt32.",
numericString);
}
// The example displays the following output:
//       Cannot convert '1293.8' to a UInt32.
//       Cannot convert '+1671.7' to a UInt32.
//       Cannot convert '28347.' to a UInt32.
//       Converted '   33113684  ' to 33113684.
//       Cannot convert '(0)' to a UInt32.
//       Converted '-0' to 0.
//       Cannot convert '-1' to a UInt32.
//       Converted '+1293617' to 1293617.
//       Cannot convert '18-' to a UInt32.
//       Converted '119870' to 119870.
//       Cannot convert '31,024' to a UInt32.
//       Converted '  3127094 ' to 3127094.
//       Converted '0070000' to 70000.
```

Remarks

The TryParse(String, UInt16) method is like the Parse(String) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `s` is invalid and cannot be successfully parsed.

The `s` parameter should be the string representation of a decimal number in the following form:

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture.
digits	A sequence of decimal digits ranging from 0 to 9.

> **Note**
>
> The string specified by the `s` parameter cannot contain any group separators or decimal separator, and it cannot have a decimal portion.

The `s` parameter is interpreted by using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces with a leading sign are allowed. To explicitly define the style elements with the culture-specific formatting information that can be present in `s`, call the TryParse(String, NumberStyles, IFormatProvider, UInt16) method.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object for the current system culture. For more information, see NumberFormatInfo.CurrentInfo.

This overload interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the TryParse(String, NumberStyles, IFormatProvider, UInt16) overload instead.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt16)

Tries to parse a span of characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out ushort result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt16

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, UInt16)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
ushort result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt16

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt16)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
ushort result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt16

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, UInt16)

Tries to convert a UTF-8 character span containing the string representation of a number to its 16-bit unsigned integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out ushort
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` UInt16

When this method returns, contains the 16-bit unsigned integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt16)

Important

This API is not CLS-compliant.

Tries to convert the span representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
ushort result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UInt16

When this method returns, contains the 16-bit unsigned integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than UInt16.MinValue or greater than UInt16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, UInt16)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int32.TryParse(String, Int32)**

Tries to convert the string representation of a number in a specified style and culture-specific format to its 16-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out ushort result);
```

Parameters

`s` String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UInt16

When this method returns, contains the 16-bit unsigned integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than UInt16.MinValue or greater than UInt16.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the TryParse(String, NumberStyles, IFormatProvider, UInt16) method with a number of different strings and NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      numericString = "10603";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      numericString = "-10603";
      styles = NumberStyles.None;
      CallTryParse(numericString, styles);
```

```
      numericString = "29103.00";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "10345.72";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "2210E-01";
      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(numericString, styles);

      numericString = "9112E-01";
      CallTryParse(numericString, styles);

      numericString = "312E01";
      CallTryParse(numericString, styles);

      numericString = "FFC8";
      CallTryParse(numericString, NumberStyles.HexNumber);

      numericString = "0x8F8C";
      CallTryParse(numericString, NumberStyles.HexNumber);
   }

   private static void CallTryParse(string stringToConvert, NumberStyles
styles)
   {
      ushort number;
      bool result = UInt16.TryParse(stringToConvert, styles,
                                    CultureInfo.InvariantCulture, out
number);
      if (result)
         Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
      else
         Console.WriteLine($"Attempted conversion of '{stringToConvert}'
failed.");
   }
}
// The example displays the following output:
//       Converted '10603' to 10603.
//       Attempted conversion of '-10603' failed.
//       Converted '29103.00' to 29103.
//       Attempted conversion of '10345.72' failed.
//       Converted '2210E-01' to 221.
//       Attempted conversion of '9112E-01' failed.
//       Converted '312E01' to 3120.
//       Converted 'FFC8' to 65480.
//       Attempted conversion of '0x8F8C' failed.
```

Remarks

The TryParse(String, NumberStyles, IFormatProvider, UInt16) method is like the Parse(String, NumberStyles, IFormatProvider) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `s` is invalid and cannot be parsed successfully.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Items in square brackets ([and]) are optional. Or, if the `style` parameter includes AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

ws Optional white space. White space can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.

$ A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.

sign An optional sign. The sign can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag. However, if the negative sign is present, `s` can only represent the value zero for the parse operation to succeed.

digits A sequence of digits from 0 through 9.

, A culture-specific group separator. The group separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.

. A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.

fractional_digits One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.

E The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.

exponential_digits A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.

hexdigits A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
None	Decimal digits only.
AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits, or the method returns `false`.
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*. If `s` represents a number in exponential notation, it cannot have a non-zero, fractional component.

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
AllowLeadingWhite	The *ws* element at the start of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element before *digits*.
AllowTrailingSign	The *sign* element after *digits*.
AllowParentheses	The *sign* element in the form of parentheses enclosing a zero numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `s`, *sign* at the start of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The *ws*, *sign*, group separator (,), and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. Valid hexadecimal digits are 0 through 9, a through f, and A through F. A prefix such as "0x" is not supported and causes the parse operation to fail. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, HexNumber, that includes both white-space flags.)

> **Note**
>
> If `s` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific

information about the format of `s`. The `provider` parameter can be any one of the following:

- A CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- A NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- A custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

UInt16.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt16.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt16.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

C#

```
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(UInt16) method.

Applies to

Product	Versions

UInt16.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt16.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The current value of this instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt16.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The current value of this instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt16.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The current value of this instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt16.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of this instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt16.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The current value of this instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1

UInt16.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSByte(IFormatProvider).

```
C#
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The current value of this instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSByte(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt16.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The current value pf this instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt16.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to which to convert this UInt16 value.

provider IFormatProvider

An IFormatProvider implementation that supplies information about the format of the returned value.

Returns

Object

The current value of this instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt16.IConvertible.To UInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The current value of this instance, unchanged.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt16.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The current value of this instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt32(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt16.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The current value of this instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt16 instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt64(UInt16) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt16.IAdditionOperators<UInt16,UInt16,UInt16>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static ushort IAdditionOperators<ushort,ushort,ushort>.operator + (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to which `right` is added.

`right` UInt16

The value that's added to `left`.

Returns

UInt16

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IAdditionOperators<UInt16,UInt16,UInt16>.CheckedAddition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static ushort IAdditionOperators<ushort,ushort,ushort>.op_CheckedAddition
(ushort left, ushort right);
```

Parameters

`left` UInt16

The value to which `right` is added.

`right` UInt16

The value that's added to `left`.

Returns

UInt16

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.IBinaryInteger<UInt16>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<ushort>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IBitwiseOperators<UInt16,UInt16,UInt16>.BitwiseAnd Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static ushort IBitwiseOperators<ushort,ushort,ushort>.operator & (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to `and` with `right`.

`right` UInt16

The value to `and` with `left`.

Returns

UInt16

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IBitwiseOperators<UInt16,UInt16,UInt16>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static ushort IBitwiseOperators<ushort,ushort,ushort>.operator | (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to `or` with `right`.

`right` UInt16

The value to `or` with `left`.

Returns

UInt16

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IBitwiseOperators<UInt16,UInt16,UInt16>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static ushort IBitwiseOperators<ushort,ushort,ushort>.operator ^ (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to xor with `right`.

`right` UInt16

The value to xor with `left`.

Returns

UInt16

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IBitwiseOperators<UInt16,UInt16,UInt16>.OnesComplement Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#

static ushort IBitwiseOperators<ushort,ushort,ushort>.operator ~ (ushort
value);
```

Parameters

`value` UInt16

The value for which to compute the ones-complement.

Returns

UInt16

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IComparisonOperators<UInt16,UInt16,Boolean>.GreaterThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<ushort,ushort,bool>.operator > (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to compare with `right`.

`right` UInt16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IComparisonOperators<UInt16,UInt16,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<ushort,ushort,bool>.operator >= (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to compare with `right`.

`right` UInt16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IComparisonOperators<UInt16,UInt16,Boolean>.LessThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<ushort,ushort,bool>.operator < (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to compare with `right`.

`right` UInt16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IComparisonOperators<UInt16,UInt16,Boolean>.LessThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<ushort,ushort,bool>.operator <= (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value to compare with `right`.

`right` UInt16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IDecrementOperators<UInt16>.CheckedDecrement(UInt16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#

static ushort IDecrementOperators<ushort>.op_CheckedDecrement (ushort
value);
```

Parameters

`value` UInt16

The value to decrement.

Returns

UInt16

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IDecrementOperators<UInt16>.Decrement(UInt16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#
static ushort IDecrementOperators<ushort>.operator -- (ushort value);
```

Parameters

`value` UInt16

The value to decrement.

Returns

UInt16

The result of decrementing `value`.

Implements

Decrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IDivisionOperators<UInt16,UInt16,UInt16>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static ushort IDivisionOperators<ushort,ushort,ushort>.operator / (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value that `right` divides.

`right` UInt16

The value that divides `left`.

Returns

UInt16

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IEqualityOperators<UInt16,UInt16,Boolean>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<ushort,ushort,bool>.operator == (ushort left,
ushort right);
```

Parameters

`left` UInt16

The value to compare with `right`.

`right` UInt16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IEqualityOperators<UInt16,UInt16,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<ushort,ushort,bool>.operator != (ushort left,
ushort right);
```

Parameters

`left` UInt16

The value to compare with `right`.

`right` UInt16

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IIncrementOperators<UInt16>.CheckedIncrement(UInt16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#

static ushort IIncrementOperators<ushort>.op_CheckedIncrement (ushort
value);
```

Parameters

`value` UInt16

The value to increment.

Returns

UInt16

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IIncrementOperators<UInt16>.Increment(UInt16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static ushort IIncrementOperators<ushort>.operator ++ (ushort value);
```

Parameters

`value` UInt16

The value to increment.

Returns

UInt16

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IMinMaxValue<UInt16>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static ushort System.Numerics.IMinMaxValue<System.UInt16>.MaxValue { get; }
```

Property Value

UInt16

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IModulusOperators<UInt16,UInt16,UInt16>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static ushort IModulusOperators<ushort,ushort,ushort>.operator % (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value that `right` divides.

`right` UInt16

The value that divides `left`.

Returns

UInt16

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IMultiplyOperators<UInt16,UInt16,UInt16>.CheckedMultiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static ushort IMultiplyOperators<ushort,ushort,ushort>.op_CheckedMultiply
(ushort left, ushort right);
```

Parameters

`left` UInt16

The value that `right` multiplies.

`right` UInt16

The value that multiplies `left`.

Returns

UInt16

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IMultiplyOperators<UInt16,UInt16,UInt16>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static ushort IMultiplyOperators<ushort,ushort,ushort>.operator * (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value that `right` multiplies.

`right` UInt16

The value that multiplies `left`.

Returns

UInt16

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumber<UInt16>.CopySign(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
static ushort INumber<ushort>.CopySign (ushort value, ushort sign);
```

Parameters

`value` UInt16

The value whose magnitude is used in the result.

`sign` UInt16

The value whose sign is used in the result.

Returns

UInt16

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumber<UInt16>.MaxNumber(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

C#

```
static ushort INumber<ushort>.MaxNumber (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumber<UInt16>.MinNumber(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

C#

```
static ushort INumber<ushort>.MinNumber (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumberBase<UInt16>.Abs(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static ushort INumberBase<ushort>.Abs (ushort value);
```

Parameters

`value` UInt16

The value for which to get its absolute.

Returns

UInt16

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.IsCanonical(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

C#

```
static bool INumberBase<ushort>.IsCanonical (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumberBase<UInt16>.IsComplexNumber(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

C#

```
static bool INumberBase<ushort>.IsComplexNumber (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumberBase<UInt16>.IsFinite(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<ushort>.IsFinite (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumberBase<UInt16>.IsImaginaryNumber(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<ushort>.IsImaginaryNumber (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumberBase<UInt16>.IsInfinity(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<ushort>.IsInfinity (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.INumberBase<UInt16>.IsInteger(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<ushort>.IsInteger (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.IsNaN(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<ushort>.IsNaN (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.IsNegative(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<ushort>.IsNegative (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.IsZero(UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<ushort>.IsZero (ushort value);
```

Parameters

`value` UInt16

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.INumberBase<UInt16>.MaxMagnitude(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static ushort INumberBase<ushort>.MaxMagnitude (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.MaxMagnitudeNumber(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

```
C#

static ushort INumberBase<ushort>.MaxMagnitudeNumber (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.MinMagnitude(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

C#

```
static ushort INumberBase<ushort>.MinMagnitude (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.MinMagnitudeNumber(UInt16, UInt16) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.

```
C#

static ushort INumberBase<ushort>.MinMagnitudeNumber (ushort x, ushort y);
```

Parameters

x UInt16

The value to compare with `y`.

y UInt16

The value to compare with `x`.

Returns

UInt16

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.INumberBase<UInt16>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<ushort>.TryConvertToChecked<TOther> (ushort value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt16

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<ushort>.TryConvertToSaturating<TOther> (ushort
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt16

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.INumberBase<UInt16>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<ushort>.TryConvertToTruncating<TOther> (ushort
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt16

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt16.IShift Operators<UInt16,Int32,UInt16>.Left Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static ushort IShiftOperators<ushort,int,ushort>.operator << (ushort value,
int shiftAmount);
```

Parameters

`value` UInt16

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

UInt16

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IShift Operators<UInt16,Int32,UInt16>.Right Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static ushort IShiftOperators<ushort,int,ushort>.operator >> (ushort value,
int shiftAmount);
```

Parameters

`value` UInt16

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt16

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IShift Operators<UInt16,Int32,UInt16>.UnsignedRightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static ushort IShiftOperators<ushort,int,ushort>.op_UnsignedRightShift
(ushort value, int shiftAmount);
```

Parameters

`value` UInt16

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt16

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.ISubtractionOperators<UInt16,UInt16,UInt16>.CheckedSubtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static ushort
ISubtractionOperators<ushort,ushort,ushort>.op_CheckedSubtraction (ushort
left, ushort right);
```

Parameters

`left` UInt16

The value from which `right` is subtracted.

`right` UInt16

The value that's subtracted from `left`.

Returns

UInt16

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.ISubtraction Operators<UInt16,UInt16,UInt16>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static ushort ISubtractionOperators<ushort,ushort,ushort>.operator - (ushort
left, ushort right);
```

Parameters

left UInt16

The value from which `right` is subtracted.

right UInt16

The value that's subtracted from `left`.

Returns

UInt16

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt16.IUnaryNegationOperators<UInt16,UInt16>.CheckedUnaryNegation Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static ushort IUnaryNegationOperators<ushort,ushort>.op_CheckedUnaryNegation
(ushort value);
```

Parameters

`value` UInt16

The value for which to compute the unary negation.

Returns

UInt16

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IUnaryNegationOperators<UInt16,UInt16>.UnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#

static ushort IUnaryNegationOperators<ushort,ushort>.operator - (ushort
value);
```

Parameters

`value` UInt16

The value for which to compute the unary negation.

Returns

UInt16

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt16.IUnaryPlusOperators<UInt16,UInt16>.UnaryPlus(UInt16) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static ushort IUnaryPlusOperators<ushort,ushort>.operator + (ushort value);
```

Parameters

`value` UInt16

The value for which to compute the unary plus.

Returns

UInt16

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IUnsignedNumber<UInt32> , IUtf8SpanFormattable ,
IUtf8SpanParsable<UInt32> , IUtf8SpanParsable<TSelf>

Remarks

The `UInt32` value type represents unsigned integers with values ranging from 0 to 4,294,967,295.

> **Important**
>
> The **UInt32** type is not CLS-compliant. The CLS-compliant alternative type is **Int64**. **Int32** can be used instead to replace a **UInt32** value that ranges from zero to **MaxValue**. For more information about CLS compliance, see **Language Independence and Language-Independent Components**.

`UInt32` provides methods to compare instances of this type, convert the value of an instance to its String representation, and convert the String representation of a number to an instance of this type.

For information about how format specification codes control the String representation of value types, see Formatting Types.

Fields

Expand table

MaxValue	Represents the largest possible value of UInt32. This field is constant.
MinValue	Represents the smallest possible value of UInt32. This field is constant.

Methods

Expand table

Clamp(UInt32, UInt32, UInt32)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.

CompareTo(UInt32)	Compares this instance to a specified 32-bit unsigned integer and returns an indication of their relative values.
CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(UInt32, UInt32)	Computes the quotient and remainder of two values.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UInt32)	Returns a value indicating whether this instance is equal to a specified UInt32.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type UInt32.
IsEvenInteger(UInt32)	Determines if a value represents an even integral number.
IsOddInteger(UInt32)	Determines if a value represents an odd integral number.
IsPow2(UInt32)	Determines if a value is a power of two.
LeadingZeroCount(UInt32)	Computes the number of leading zeros in a value.
Log2(UInt32)	Computes the log2 of a value.
Max(UInt32, UInt32)	Compares two values to compute which is greater.
Min(UInt32, UInt32)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit unsigned

	integer equivalent.
Parse(String)	Converts the string representation of a number to its 32-bit unsigned integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 32-bit unsigned integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 32-bit unsigned integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent.
PopCount(UInt32)	Computes the number of bits that are set in a value.
RotateLeft(UInt32, Int32)	Rotates a value left by a given amount.
RotateRight(UInt32, Int32)	Rotates a value right by a given amount.
Sign(UInt32)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
TrailingZeroCount(UInt32)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current unsigned integer number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider,	Tries to parse a span of UTF-8 characters into a value.

UInt32)	
TryParse(ReadOnlySpan<Byte>, UInt32)	Tries to convert a UTF-8 character span containing the string representation of a number to its 32-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt32)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt32)	Tries to convert the span representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, UInt32)	Tries to convert the span representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, UInt32)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, UInt32)	Tries to convert the string representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, UInt32)	Tries to convert the string representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<UInt32,UInt32,UInt32>.Addition(UInt32, UInt32)	Adds two values together to compute their sum.
IAdditionOperators<UInt32,UInt32,UInt32>.CheckedAddition(UInt32, UInt32)	Adds two values together to compute their sum.
IAdditiveIdentity<UInt32,UInt32>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<UInt32>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).

IBinaryInteger<UInt32>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<UInt32>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, UInt32)	
IBinaryInteger<UInt32>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, UInt32)	
IBinaryInteger<UInt32>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<UInt32>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<UInt32>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<UInt32,UInt32,UInt32>.BitwiseAnd(UInt32, UInt32)	Computes the bitwise-and of two values.
IBitwiseOperators<UInt32,UInt32,UInt32>.BitwiseOr(UInt32, UInt32)	Computes the bitwise-or of two values.
IBitwiseOperators<UInt32,UInt32,UInt32>.ExclusiveOr(UInt32, UInt32)	Computes the exclusive-or of two values.
IBitwiseOperators<UInt32,UInt32,UInt32>.OnesComplement(UInt32)	Computes the ones-complement representation of a given value.
IComparisonOperators<UInt32,UInt32,Boolean>.GreaterThan(UInt32, UInt32)	Compares two values to determine which is greater.
IComparisonOperators<UInt32,UInt32,Boolean>.GreaterThanOrEqual(UInt32, UInt32)	Compares two values to determine which is greater or equal.
IComparisonOperators<UInt32,UInt32,Boolean>.LessThan(UInt32, UInt32)	Compares two values to determine which is less.
IComparisonOperators<UInt32,UInt32,Boolean>.LessThanOrEqual(UInt32, UInt32)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).

IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.
IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<UInt32>.CheckedDecrement(UInt32)	Decrements a value.
IDecrementOperators<UInt32>.Decrement(UInt32)	Decrements a value.
IDivisionOperators<UInt32,UInt32,UInt32>.Division(UInt32, UInt32)	Divides one value by another to compute their quotient.
IEqualityOperators<UInt32,UInt32,Boolean>.Equality(UInt32, UInt32)	Compares two values to determine equality.
IEqualityOperators<UInt32,UInt32,Boolean>.Inequality(UInt32, UInt32)	Compares two values to determine inequality.
IIncrementOperators<UInt32>.CheckedIncrement(UInt32)	Increments a value.

IIncrementOperators<UInt32>.Increment(UInt32)	Increments a value.
IMinMaxValue<UInt32>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<UInt32>.MinValue	Gets the minimum value of the current type.
IModulus Operators<UInt32,UInt32,UInt32>.Modulus(UInt32, UInt32)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<UInt32,UInt32>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiplyOperators<UInt32,UInt32,UInt32>.Checked Multiply(UInt32, UInt32)	Multiplies two values together to compute their product.
IMultiplyOperators<UInt32,UInt32,UInt32>.Multiply(UInt32, UInt32)	Multiplies two values together to compute their product.
INumber<UInt32>.CopySign(UInt32, UInt32)	Copies the sign of a value to the sign of another value.
INumber<UInt32>.MaxNumber(UInt32, UInt32)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<UInt32>.MinNumber(UInt32, UInt32)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<UInt32>.Abs(UInt32)	Computes the absolute of a value.
INumberBase<UInt32>.IsCanonical(UInt32)	Determines if a value is in its canonical representation.
INumberBase<UInt32>.IsComplexNumber(UInt32)	Determines if a value represents a complex number.
INumberBase<UInt32>.IsFinite(UInt32)	Determines if a value is finite.
INumberBase<UInt32>.IsImaginaryNumber(UInt32)	Determines if a value represents a pure imaginary number.
INumberBase<UInt32>.IsInfinity(UInt32)	Determines if a value is infinite.
INumberBase<UInt32>.IsInteger(UInt32)	Determines if a value represents an integral number.
INumberBase<UInt32>.IsNaN(UInt32)	Determines if a value is NaN.

INumberBase<UInt32>.IsNegative(UInt32)	Determines if a value is negative.
INumberBase<UInt32>.IsNegativeInfinity(UInt32)	Determines if a value is negative infinity.
INumberBase<UInt32>.IsNormal(UInt32)	Determines if a value is normal.
INumberBase<UInt32>.IsPositive(UInt32)	Determines if a value is positive.
INumberBase<UInt32>.IsPositiveInfinity(UInt32)	Determines if a value is positive infinity.
INumberBase<UInt32>.IsRealNumber(UInt32)	Determines if a value represents a real number.
INumberBase<UInt32>.IsSubnormal(UInt32)	Determines if a value is subnormal.
INumberBase<UInt32>.IsZero(UInt32)	Determines if a value is zero.
INumberBase<UInt32>.MaxMagnitude(UInt32, UInt32)	Compares two values to compute which is greater.
INumberBase<UInt32>.MaxMagnitudeNumber(UInt32, UInt32)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt32>.MinMagnitude(UInt32, UInt32)	Compares two values to compute which is lesser.
INumberBase<UInt32>.MinMagnitudeNumber(UInt32, UInt32)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt32>.One	Gets the value `1` for the type.
INumberBase<UInt32>.Radix	Gets the radix, or base, for the type.
INumberBase<UInt32>.TryConvertFromChecked<TOther>(TOther, UInt32)	
INumberBase<UInt32>.TryConvertFromSaturating<TOther>(TOther, UInt32)	
INumberBase<UInt32>.TryConvertFromTruncating<TOther>(TOther, UInt32)	
INumberBase<UInt32>.TryConvertToChecked<TOther>(UInt32, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

INumberBase<UInt32>.TryConvertToSaturating<TOther>(UInt32, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<UInt32>.TryConvertToTruncating<TOther>(UInt32, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<UInt32>.Zero	Gets the value `0` for the type.
IShiftOperators<UInt32,Int32,UInt32>.LeftShift(UInt32, Int32)	Shifts a value left by a given amount.
IShiftOperators<UInt32,Int32,UInt32>.RightShift(UInt32, Int32)	Shifts a value right by a given amount.
IShiftOperators<UInt32,Int32,UInt32>.UnsignedRightShift(UInt32, Int32)	Shifts a value right by a given amount.
ISubtractionOperators<UInt32,UInt32,UInt32>.CheckedSubtraction(UInt32, UInt32)	Subtracts two values to compute their difference.
ISubtractionOperators<UInt32,UInt32,UInt32>.Subtraction(UInt32, UInt32)	Subtracts two values to compute their difference.
IUnaryNegationOperators<UInt32,UInt32>.CheckedUnaryNegation(UInt32)	Computes the checked unary negation of a value.
IUnaryNegationOperators<UInt32,UInt32>.UnaryNegation(UInt32)	Computes the unary negation of a value.
IUnaryPlusOperators<UInt32,UInt32>.UnaryPlus(UInt32)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

UInt32.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of UInt32. This field is constant.

C#

```
public const uint MaxValue = 4294967295;
```

Field Value

Value* = *4294967295

UInt32

Examples

The following example uses the MinValue and MaxValue fields to verify that an Int64 value is within the range of the UInt32 type before it performs a type conversion. This verification prevents an OverflowException at run time.

C#

```
long longValue = long.MaxValue / 2;
uint integerValue;

if (longValue <= uint.MaxValue &&
    longValue >= uint.MinValue)
{
   integerValue = (uint) longValue;
   Console.WriteLine("Converted long integer value to {0:n0}.",
                     integerValue);
}
else
{
   uint rangeLimit;
   string relationship;

   if (longValue > uint.MaxValue)
   {
```

```
        rangeLimit = uint.MaxValue;
        relationship = "greater";
    }
    else
    {
        rangeLimit = uint.MinValue;
        relationship = "less";
    }

    Console.WriteLine("Conversion failure: {0:n0} is {1} than {2:n0}",
                      longValue,
                      relationship,
                      rangeLimit);
}
```

Remarks

The value of this constant is 4,294,967,295; that is, hexadecimal 0xFFFFFFFF.

Applies to

Product	Versions

UInt32.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of UInt32. This field is constant.

C#

```
public const uint MinValue = 0;
```

Field Value

***Value* = 0**

UInt32

Examples

The following example demonstrates how to use the MinValue field to display the smallest possible value of a UInt32 variable.

C#

```
public class Temperature {
    public static uint MinValue {
        get {
            return UInt32.MinValue;
        }
    }

    public static uint MaxValue {
        get {
            return UInt32.MaxValue;
        }
    }

    // The value holder
    protected uint m_value;

    public uint Value {
        get {
```

```
            return m_value;
        }
        set {
            m_value = value;
        }
    }
}
```

Remarks

The value of this constant is 0.

UInt32.Clamp(UInt32, UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static uint Clamp (uint value, uint min, uint max);
```

Parameters

`value` UInt32

The value to clamp.

`min` UInt32

The inclusive minimum to which `value` should clamp.

`max` UInt32

The inclusive maximum to which `value` should clamp.

Returns

UInt32

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or UInt32 and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CompareTo(UInt32)	Compares this instance to a specified 32-bit unsigned integer and returns an indication of their relative values.

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

value Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a UInt32.

Examples

The following code example demonstrates the CompareTo method.

C#

```
public class Temperature : IComparable {
    /// <summary>
    /// IComparable.CompareTo implementation.
    /// </summary>
    public int CompareTo(object obj) {
        if(obj is Temperature) {
            Temperature temp = (Temperature) obj;

            return m_value.CompareTo(temp.m_value);
        }

        throw new ArgumentException("object is not a Temperature");
    }

    // The value holder
    protected uint m_value;

    public uint Value {
        get {
            return m_value;
        }
```

```
        set {
            m_value = value;
        }
    }
}
```

Remarks

Any instance of UInt32, regardless of its value, is considered greater than `null`.

The `value` parameter must be `null` or an instance of UInt32; otherwise, an exception is thrown.

See also

- Equals(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CompareTo(UInt32)

Compares this instance to a specified 32-bit unsigned integer and returns an indication of their relative values.

C#

```
public int CompareTo (uint value);
```

Parameters

`value` UInt32

An unsigned integer to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";
```

```

y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
```

```
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the UInt32.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

UInt32.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static uint CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt32

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static uint CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt32

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.CreateTruncating<TOther> (TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static uint CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

TOther

The type of `value`.

Parameters

value TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt32

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.DivRem(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (uint Quotient, uint Remainder) DivRem (uint left, uint
right);
```

Parameters

`left` UInt32

The value which `right` divides.

`right` UInt32

The value which divides `left`.

Returns

ValueTuple<UInt32,UInt32>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or UInt32.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UInt32)	Returns a value indicating whether this instance is equal to a specified UInt32.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance.

Returns

Boolean

`true` if `obj` is an instance of UInt32 and equals the value of this instance; otherwise, `false`.

Examples

The following code example demonstrates the Equals method.

C#

```
UInt32 myVariable1 = 20;
UInt32 myVariable2 = 20;

// Display the declaring type.
Console.WriteLine("\nType of 'myVariable1' is '{0}' and"+
     " value is :{1}",myVariable1.GetType(), myVariable1);
Console.WriteLine("Type of 'myVariable2' is '{0}' and"+
     " value is :{1}",myVariable2.GetType(), myVariable2);

// Compare 'myVariable1' instance with 'myVariable2' Object.
if( myVariable1.Equals( myVariable2 ) )
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are equal");
else
   Console.WriteLine( "\nStructures 'myVariable1' and "+
         "'myVariable2' are not equal");
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(UInt32) method overloads. If an implicit conversion between the `obj` argument and a UInt32 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(UInt32) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a UInt32 value. The following example illustrates the difference in behavior between the two method overloads. In the case of Byte and UInt16 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(UInt32) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static uint value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);
```

```
        short short1 = 112;
        Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
        TestObjectForEquality(short1);

        long long1 = 112;
        Console.WriteLine("value = long1: {0,18}", value.Equals(long1));
        TestObjectForEquality(long1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,18}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:              True
//       112 (UInt32) = 112 (Byte): False
//
//       value = short1:              False
//       112 (UInt32) = 112 (Int16): False
//
//       value = long1:               False
//       112 (UInt32) = 112 (Int64): False
//
//       value = sbyte1:              False
//       112 (UInt32) = 112 (SByte): False
//
//       value = ushort1:              True
//       112 (UInt32) = 112 (UInt16): False
//
//       value = ulong1:                False
```

```
//       112 (UInt32) = 112 (UInt64): False
//
//       value = dec1:                 False
//       112 (UInt32) = 112 (Decimal): False
//
//       value = dbl1:                False
//       112 (UInt32) = 112 (Double): False
```

Equals(UInt32)

Returns a value indicating whether this instance is equal to a specified UInt32.

C#

```
public bool Equals (uint obj);
```

Parameters

obj UInt32

A value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than the Equals(Object) method because it does not have to convert the `obj` parameter to an object.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(UInt32) method overloads. If an implicit conversion between the `obj` argument and a UInt32 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(UInt32) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a UInt32 value. The following example illustrates the difference in behavior between the two method overloads. In the case of Byte and UInt16 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(UInt32) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static uint value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
      TestObjectForEquality(short1);

      long long1 = 112;
      Console.WriteLine("value = long1: {0,18}", value.Equals(long1));
```

```
        TestObjectForEquality(long1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        ulong ulong1 = 112;
        Console.WriteLine("value = ulong1: {0,18}", value.Equals(ulong1));
        TestObjectForEquality(ulong1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (UInt32) = 112 (Byte): False
//
//       value = short1:             False
//       112 (UInt32) = 112 (Int16): False
//
//       value = long1:              False
//       112 (UInt32) = 112 (Int64): False
//
//       value = sbyte1:             False
//       112 (UInt32) = 112 (SByte): False
//
//       value = ushort1:             True
//       112 (UInt32) = 112 (UInt16): False
//
//       value = ulong1:               False
//       112 (UInt32) = 112 (UInt64): False
//
//       value = dec1:                 False
//       112 (UInt32) = 112 (Decimal): False
//
```

```
//       value = dbl1:                False
//       112 (UInt32) = 112 (Double): False

UInt32.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type UInt32.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, UInt32.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt32.IsEvenInteger(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IsOddInteger(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

UInt32.IsPow2(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.LeadingZeroCount(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

```
C#
public static uint LeadingZeroCount (uint value);
```

Parameters

`value` UInt32

The value whose leading zeroes are to be counted.

Returns

UInt32

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.Log2(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static uint Log2 (uint value);
```

Parameters

`value` UInt32

The value whose log2 is to be computed.

Returns

UInt32

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.Max(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static uint Max (uint x, uint y);
```

Parameters

x UInt32

The value to compare with `y`.

y UInt32

The value to compare with `x`.

Returns

UInt32

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.Min(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static uint Min (uint x, uint y);
```

Parameters

x UInt32

The value to compare with `y`.

y UInt32

The value to compare with `x`.

Returns

UInt32

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 32-bit unsigned integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 32-bit unsigned integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 32-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String)	Converts the string representation of a number to its 32-bit unsigned integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int64.Parse(String)**

Converts the string representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent.

C#

```
public static uint Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string representing the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt32

A 32-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example uses the Parse(String, NumberStyles, IFormatProvider) method to convert various string representations of numbers to 32-bit unsigned integer values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] cultureNames= { "en-US", "fr-FR" };
      NumberStyles[] styles= { NumberStyles.Integer,
                               NumberStyles.Integer |
NumberStyles.AllowDecimalPoint };
      string[] values = { "170209", "+170209.0", "+170209,0",
"-103214.00",
                                  "-103214,00", "104561.1", "104561,1" };

      // Parse strings using each culture
      foreach (string cultureName in cultureNames)
      {
         CultureInfo ci = new CultureInfo(cultureName);
         Console.WriteLine("Parsing strings using the {0} culture",
                           ci.DisplayName);
         // Use each style.
```

```
         foreach (NumberStyles style in styles)
         {
            Console.WriteLine("   Style: {0}", style.ToString());
            // Parse each numeric string.
            foreach (string value in values)
            {
               try {
                  Console.WriteLine("      Converted '{0}' to {1}.",
value,
                                    UInt32.Parse(value, style, ci));
               }
               catch (FormatException) {
                  Console.WriteLine("      Unable to parse '{0}'.",
value);
               }
               catch (OverflowException) {
                  Console.WriteLine("      '{0}' is out of range of the
UInt32 type.",
                                    value);
               }
            }
         }
      }
   }
}
// The example displays the following output:
//       Parsing strings using the English (United States) culture
//          Style: Integer
//             Converted '170209' to 170209.
//             Unable to parse '+170209.0'.
//             Unable to parse '+170209,0'.
//             Unable to parse '-103214.00'.
//             Unable to parse '-103214,00'.
//             Unable to parse '104561.1'.
//             Unable to parse '104561,1'.
//          Style: Integer, AllowDecimalPoint
//             Converted '170209' to 170209.
//             Converted '+170209.0' to 170209.
//             Unable to parse '+170209,0'.
//             '-103214.00' is out of range of the UInt32 type.
//             Unable to parse '-103214,00'.
//             '104561.1' is out of range of the UInt32 type.
//             Unable to parse '104561,1'.
//       Parsing strings using the French (France) culture
//          Style: Integer
//             Converted '170209' to 170209.
//             Unable to parse '+170209.0'.
//             Unable to parse '+170209,0'.
//             Unable to parse '-103214.00'.
//             Unable to parse '-103214,00'.
//             Unable to parse '104561.1'.
//             Unable to parse '104561,1'.
//          Style: Integer, AllowDecimalPoint
//             Converted '170209' to 170209.
//             Unable to parse '+170209.0'.
```

```
//              Converted '+170209,0' to 170209.
//              Unable to parse '-103214.00'.
//              '-103214,00' is out of range of the UInt32 type.
//              Unable to parse '104561.1'.
//              '104561,1' is out of range of the UInt32 type.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive or negative sign symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Elements in square brackets ([and]) are optional. If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object that is returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. (The method throws an OverflowException if `s` includes a negative sign and represents a non-zero number.) The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can

Element	Description
	be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0-9 if `style` includes the NumberStyles.AllowExponent flag, or one or more occurrences of the digit 0 if it does not. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, if style does not include the

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
	NumberStyles.AllowExponent flag, *fractional_digits* must consist of only one or more 0 digits; otherwise, an OverflowException is thrown.
NumberStyles.AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign before *digits*.
NumberStyles.AllowTrailingSign	A sign after *digits*.
NumberStyles.AllowParentheses	Parentheses before and after *digits* to indicate a negative value.
NumberStyles.AllowThousands	The group separator (,) element.
NumberStyles.AllowCurrencySymbol	The currency ($) element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. The only other flags that can be combined with it are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

> **Note**
>
> If the `s` parameter is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the parse operation to throw an exception.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)

- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the span representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent.

```
C#
```

```
public static uint Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt32

A 32-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static uint Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt32

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

Important

This API is not CLS-compliant.

CLS-compliant alternative **System.Int64.Parse(String)**

Converts the string representation of a number in a specified culture-specific format to its 32-bit unsigned integer equivalent.

C#

```
public static uint Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that represents the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt32

A 32-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct style.

OverflowException

`s` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to a UInt32 value.

C#

```
protected void OkToUInteger_Click(object sender, EventArgs e)
{
    string locale;
    uint number;
    CultureInfo culture;

    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;

    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = UInt32.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
        return;
    }
    catch (Exception)
    {
        return;
    }
    // Output number to label on web form
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

The `s` parameter contains a number of the form:

[*ws*][*sign*]*digits*[*ws*]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign, or a negative sign if `s` represents the value zero.
digits	A sequence of digits ranging from 0 to 9.

The s parameter is interpreted using the NumberStyles.Integer style. In addition to the unsigned integer value's decimal digits, only leading and trailing spaces along with a leading sign is allowed. (If the negative sign is present, `s` must represent a value of zero, or the method throws an OverflowException.) To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo for the current culture is used.

Parse(String, NumberStyles)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int64.Parse(String)**

Converts the string representation of a number in a specified style to its 32-bit unsigned integer equivalent.

C#

```
public static uint Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string representing the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of the enumeration values that specify the permitted format of `s`. A typical value to specify is Integer.

Returns

UInt32

A 32-bit unsigned integer equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in a format compliant with `style`.

OverflowException

`s` represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example tries to parse each element in a string array by using a number of NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
```

```
   public static void Main()
   {
      string[] values= { " 214309 ", "1,064,181", "(0)", "10241+", " +
21499 ",
                         " +21499 ", "122153.00", "1e03ff", "91300.0e-2"
};
      NumberStyles whitespace =  NumberStyles.AllowLeadingWhite |
NumberStyles.AllowTrailingWhite;
      NumberStyles[] styles= { NumberStyles.None, whitespace,
                               NumberStyles.AllowLeadingSign |
NumberStyles.AllowTrailingSign | whitespace,
                               NumberStyles.AllowThousands |
NumberStyles.AllowCurrencySymbol,
                               NumberStyles.AllowExponent |
NumberStyles.AllowDecimalPoint };

      // Attempt to convert each number using each style combination.
      foreach (string value in values)
      {
         Console.WriteLine("Attempting to convert '{0}':", value);
         foreach (NumberStyles style in styles)
         {
            try {
               uint number = UInt32.Parse(value, style);
               Console.WriteLine("   {0}: {1}", style, number);
            }
            catch (FormatException) {
               Console.WriteLine("   {0}: Bad Format", style);
            }
            catch (OverflowException)
            {
               Console.WriteLine("   {0}: Overflow", value);
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    Attempting to convert ' 214309 ':

//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: 913
```

Remarks

The `style` parameter defines the style elements (such as white space, the positive or negative sign symbol, the group separator symbol, or the decimal point symbol) that

are allowed in the `s` parameter for the parse operation to succeed. `style` must be a combination of bit flags from the NumberStyles enumeration. The `style` parameter makes this method overload useful when `s` contains the string representation of a hexadecimal value, when the number system (decimal or hexadecimal) represented by `s` is known only at run time, or when you want to disallow white space or a sign symbol in `s`.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Elements in square brackets ([and]) are optional. If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may contain the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag. However, the negative sign symbol can be used only with zero; otherwise, the method throws an OverflowException.
digits *fractional_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.

Element	Description
exponential_digits	
,	A culture-specific group separator symbol. The current culture's group separator can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, a FormatException is thrown.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the UInt32 type. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

`NumberStyles` value	Elements permitted in `s` in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
AllowLeadingWhite	The *ws* element at the start of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.

`NumberStyles` value	Elements permitted in `s` in addition to digits
AllowLeadingSign	The *sign* element at the start of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `s`, *sign* at the start of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, group separator (,), and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

Unlike the other NumberStyles values, which allow for, but do not require, the presence of particular style elements in `s`, the NumberStyles.AllowHexSpecifier style value means that the individual numeric characters in `s` are always interpreted as hexadecimal characters. Valid hexadecimal characters are 0-9, A-F, and a-f. A prefix, such as "0x", is not allowed. The only other flags that can be combined with the `style` parameter are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

The only other flags that can be combined with the `style` parameter are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

> **Note**
>
> If `s` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To specify the culture whose formatting information is used for the parse operation, call the Parse(String, NumberStyles, IFormatProvider) overload.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static uint Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt32

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

C#

```
public static uint Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt32

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int64.Parse(String)**

Converts the string representation of a number to its 32-bit unsigned integer equivalent.

C#

```
public static uint Parse (string s);
```

Parameters

s String

A string representing the number to convert.

Returns

UInt32

A 32-bit unsigned integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

The `s` parameter is `null`.

FormatException

The `s` parameter is not of the correct format.

OverflowException

The `s` parameter represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue.

Examples

The following example uses the Parse(String) method to parse an array of string values.

C#

```
string[] values = { "+13230", "-0", "1,390,146", "$190,235,421,127",
                    "0xFA1B", "163042", "-10", "2147483648",
                    "14065839182", "16e07", "134985.0", "-12034" };
foreach (string value in values)
{
   try {
      uint number = UInt32.Parse(value);
      Console.WriteLine("{0} --> {1}", value, number);
   }
   catch (FormatException) {
      Console.WriteLine("{0}: Bad Format", value);
   }
   catch (OverflowException) {
      Console.WriteLine("{0}: Overflow", value);
   }
}
// The example displays the following output:
//       +13230 --> 13230
//       -0 --> 0
//       1,390,146: Bad Format
//       $190,235,421,127: Bad Format
//       0xFA1B: Bad Format
//       163042 --> 163042
//       -10: Overflow
//       2147483648 --> 2147483648
//       14065839182: Overflow
//       16e07: Bad Format
//       134985.0: Bad Format
//       -12034: Overflow
```

Remarks

The `s` parameter should be the string representation of a number in the following form.

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture. However, the negative sign symbol can be used only with zero; otherwise, the method throws an OverflowException.
digits	A sequence of digits ranging from 0 to 9. Any leading zeros are ignored.

> **Note**
>
> The string specified by the `s` parameter is interpreted by using the **NumberStyles.Integer** style. It cannot contain any group separators or decimal separator, and it cannot have a decimal portion.

The `s` parameter is parsed by using the formatting information in a System.Globalization.NumberFormatInfo object that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse a string by using the formatting information of a specific culture, use the Parse(String, IFormatProvider) method.

UInt32.PopCount(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

```
C#
public static uint PopCount (uint value);
```

Parameters

`value` UInt32

The value whose set bits are to be counted.

Returns

UInt32

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.RotateLeft(UInt32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static uint RotateLeft (uint value, int rotateAmount);
```

Parameters

`value` UInt32

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

UInt32

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.RotateRight(UInt32, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

C#

```
public static uint RotateRight (uint value, int rotateAmount);
```

Parameters

`value` UInt32

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

UInt32

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.Sign(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (uint value);
```

Parameters

`value` UInt32

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString()	Converts the numeric value of this instance to its equivalent string representation.

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance, which consists of a sequence of digits ranging from 0 to 9, without a sign or leading zeros.

Implements

ToString(IFormatProvider)

Examples

The following example formats a 16-bit signed integer value by using several format providers, including one for the invariant culture. The output from the example illustrates that the formatted string returned by the ToString(IFormatProvider) method is the same regardless of the format provider.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define an array of CultureInfo objects.
      CultureInfo[] ci = { new CultureInfo("en-US"),
                           new CultureInfo("fr-FR"),
                           CultureInfo.InvariantCulture };
      uint value = 1870924;
      Console.WriteLine("  {0,12}   {1,12}   {2,12}",
                        GetName(ci[0]), GetName(ci[1]), GetName(ci[2]));
      Console.WriteLine("  {0,12}   {1,12}   {2,12}",
                        value.ToString(ci[0]), value.ToString(ci[1]),
value.ToString(ci[2]));
   }

   private static string GetName(CultureInfo ci)
   {
      if (ci.Equals(CultureInfo.InvariantCulture))
         return "Invariant";
      else
         return ci.Name;
   }
}
```

```
// The example displays the following output:
//              en-US          fr-FR      Invariant
//            1870924        1870924        1870924
```

Remarks

The ToString(IFormatProvider) method formats a UInt32 value in the default ("G", or general) format by using the NumberFormatInfo object of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific formatting information. However, none of the properties of the NumberFormatInfo are used when formatting with the general numeric format specifier ("G").

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

The `format` parameter is invalid.

Examples

The following example displays a 32-bit unsigned integer value by using each standard format string and some custom format strings.

```
C#

using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
```

```
        uint value = 2179608;
        string[] specifiers = { "G", "C", "D3", "E2", "e3", "F",
                                "N", "P", "X", "000000.0", "#.0",
                                "00000000;(0);**Zero**" };

        foreach (string specifier in specifiers)
           Console.WriteLine("{0}: {1}", specifier,
value.ToString(specifier));
    }
}
// The example displays the following output:
//       G: 2179608
//       C: $2,179,608.00
//       D3: 2179608
//       E2: 2.18E+006
//       e3: 2.180e+006
//       F: 2179608.00
//       N: 2,179,608.00
//       P: 217,960,800.00 %
//       X: 214218
//       000000.0: 2179608.0
//       #.0: 2179608.0
//       00000000;(0);**Zero**: 02179608
```

Remarks

The ToString(String) method formats a UInt32 value in a specified format by using a NumberFormatInfo object that represents the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be any valid Standard Numeric Format Strings, or any combination of Custom Numeric Format Strings. If `format` is equal to String.Empty or is `null`, the return value of the current UInt32 object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

The format of the returned string is determined by the NumberFormatInfo object for the current culture. Depending on the `format` parameter, this object controls symbols such as the group separator and the decimal point symbol in the output string. To provide formatting information for cultures other than the current culture, call the ToString(String, IFormatProvider) overload.

UWP	10.0

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

```
C#
```

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about this instance.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

The `format` parameter is invalid.

Examples

The following example displays a 32-bit unsigned integer value by using the standard numeric format specifiers and a number of specific CultureInfo objects.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define cultures whose formatting conventions are to be used.
      CultureInfo[] cultures = { CultureInfo.CreateSpecificCulture("en-
US"),
```

```
                                    CultureInfo.CreateSpecificCulture("fr-
FR"),
                                    CultureInfo.CreateSpecificCulture("es-
ES") };
      string[] specifiers = {"G", "C", "D4", "E2", "F", "N", "P", "X2"};
      uint value = 2222402;

      foreach (string specifier in specifiers)
      {
         foreach (CultureInfo culture in cultures)
            Console.WriteLine("{0,2} format using {1} culture: {2, 18}",
                              specifier, culture.Name,
                              value.ToString(specifier, culture));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//        G format using en-US culture:            2222402
//        G format using fr-FR culture:            2222402
//        G format using es-ES culture:            2222402
//
//        C format using en-US culture:      $2,222,402.00
//        C format using fr-FR culture:     2 222 402,00 €
//        C format using es-ES culture:     2.222.402,00 €
//
//       D4 format using en-US culture:            2222402
//       D4 format using fr-FR culture:            2222402
//       D4 format using es-ES culture:            2222402
//
//       E2 format using en-US culture:          2.22E+006
//       E2 format using fr-FR culture:          2,22E+006
//       E2 format using es-ES culture:          2,22E+006
//
//        F format using en-US culture:         2222402.00
//        F format using fr-FR culture:         2222402,00
//        F format using es-ES culture:         2222402,00
//
//        N format using en-US culture:       2,222,402.00
//        N format using fr-FR culture:       2 222 402,00
//        N format using es-ES culture:       2.222.402,00
//
//        P format using en-US culture:   222,240,200.00 %
//        P format using fr-FR culture:   222 240 200,00 %
//        P format using es-ES culture:   222.240.200,00 %
//
//       X2 format using en-US culture:             21E942
//       X2 format using fr-FR culture:             21E942
//       X2 format using es-ES culture:             21E942
```

Remarks

The ToString(String, IFormatProvider) method formats a UInt32 value in a specified format by using the NumberFormatInfo object of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be any valid Standard Numeric Format Strings, or any combination of Custom Numeric Format Strings. If `format` is equal to String.Empty or is `null`, the return value of the current UInt32 object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string returned by this method. When the ToString(String, IFormatProvider) method is invoked, it calls the `provider` parameter's IFormatProvider.GetFormat method and passes it a Type object that represents the NumberFormatInfo type. The GetFormat method then returns the NumberFormatInfo object that provides information for formatting the current UInt32 value, such as the group separator symbol or the decimal point symbol. There are three ways to use the `provider` parameter to supply formatting information to the ToString(String, IFormatProvider) method:

- You can pass a CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.

- You can pass the actual NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- You can pass a custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the formatting of the returned string is based on the NumberFormatInfo object of the current culture.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, consisting of a sequence of digits ranging from 0 to 9, without a sign or leading zeroes.

Examples

The following example displays a UInt32 value by using the default ToString() method. It also displays the string representations of the UInt32 value that results from using some standard format specifiers. The examples are displayed using the formatting conventions of the en-US culture.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      uint value = 1632490;
      // Display value using default ToString method.
      Console.WriteLine(value.ToString());
      Console.WriteLine();

      // Define an array of format specifiers.
      string[] formats = { "G", "C", "D", "F", "N", "X" };
      // Display value using the standard format specifiers.
      foreach (string format in formats)
         Console.WriteLine("{0} format specifier: {1,16}",
                           format, value.ToString(format));
   }
}
// The example displays the following output:
//       1632490
//
//       G format specifier:          1632490
//       C format specifier:    $1,632,490.00
//       D format specifier:          1632490
//       F format specifier:       1632490.00
//       N format specifier:     1,632,490.00
//       X format specifier:           18E8EA
```

Remarks

The ToString() method formats a UInt32 value in the default ("G", or general) format by using the NumberFormatInfo object of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

UInt32.TrailingZeroCount(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static uint TrailingZeroCount (uint value);
```

Parameters

`value` UInt32

The value whose trailing zeroes are to be counted.

Returns

UInt32

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current unsigned integer number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current unsigned integer number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

UInt32.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the string representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, UInt32)	Tries to convert the span representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, UInt32)	Tries to convert the string representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt32)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, UInt32)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt32)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, UInt32)	Tries to convert a UTF-8 character span containing the string representation of a number to its 32-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt32)	Tries to convert the span representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(String, NumberStyles, IFormatProvider, UInt32)	Tries to convert the string representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt32)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out uint result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt32

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, UInt32)

> Important
>
> This API is not CLS-compliant.

Tries to convert the span representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out uint result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert.

`result` UInt32

When this method returns, contains the 32-bit unsigned integer value that is equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, UInt32)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int64.TryParse(String, Int64)**

Tries to convert the string representation of a number to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (string? s, out uint result);
```

Parameters

`s` String

A string that represents the number to convert.

`result` UInt32

When this method returns, contains the 32-bit unsigned integer value that is equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParse(String, UInt32) method once for each element in a string array.

```
C#
```

```
string[] numericStrings = { "1293.8", "+1671.7", "28347.",
                            "   33113684  ", "(0)", "-0", "-1",
                            "+1293617", "18-", "119870", "31,024",
                            "  3127094 ", "00700000" };
uint number;
foreach (string numericString in numericStrings)
{
   if (UInt32.TryParse(numericString, out number))
      Console.WriteLine("Converted '{0}' to {1}.", numericString,
number);
   else
      Console.WriteLine("Cannot convert '{0}' to a UInt32.",
numericString);
}
// The example displays the following output:
//       Cannot convert '1293.8' to a UInt32.
//       Cannot convert '+1671.7' to a UInt32.
//       Cannot convert '28347.' to a UInt32.
//       Converted '   33113684  ' to 33113684.
//       Cannot convert '(0)' to a UInt32.
//       Converted '-0' to 0.
//       Cannot convert '-1' to a UInt32.
//       Converted '+1293617' to 1293617.
//       Cannot convert '18-' to a UInt32.
//       Converted '119870' to 119870.
//       Cannot convert '31,024' to a UInt32.
//       Converted '  3127094 ' to 3127094.
//       Converted '0070000' to 70000.
```

Remarks

The TryParse method is like the Parse method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `s` is invalid and cannot be successfully parsed.

The `s` parameter should be the string representation of a decimal number in the following form:

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture.
digits	A sequence of decimal digits ranging from 0 to 9.

The `s` parameter is interpreted by using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces with a leading sign are allowed. To explicitly define the style elements with the culture-specific formatting information that can be present in `s`, call the TryParse(String, NumberStyles, IFormatProvider, UInt32) method.

> **Note**
>
> The string specified by the `s` parameter cannot contain any group separators or decimal separator, and it cannot have a fractional portion.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object for the current system culture. For more information, see NumberFormatInfo.CurrentInfo.

This overload interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the TryParse(String, NumberStyles, IFormatProvider, UInt32) overload instead.

TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt32)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out uint result);
```

Parameters

s ReadOnlySpan<Char>

The span of characters to parse.

provider IFormatProvider

An object that provides culture-specific formatting information about `s`.

result UInt32

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, UInt32)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
uint result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt32

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt32)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
uint result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt32

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, UInt32)

Tries to convert a UTF-8 character span containing the string representation of a number to its 32-bit unsigned integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out uint
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` UInt32

When this method returns, contains the 32-bit unsigned integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt32)

Important

This API is not CLS-compliant.

Tries to convert the span representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```C#
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
uint result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UInt32

When this method returns, contains the 32-bit unsigned integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, UInt32)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Int64.TryParse(String, Int64)**

Tries to convert the string representation of a number in a specified style and culture-specific format to its 32-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out uint result);
```

Parameters

`s` String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UInt32

When this method returns, contains the 32-bit unsigned integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number that is less than UInt32.MinValue or greater than UInt32.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the TryParse(String, NumberStyles, IFormatProvider, UInt32) method with a number of different strings and NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      numericString = "2106034";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      numericString = "-10603";
      styles = NumberStyles.None;
      CallTryParse(numericString, styles);
```

```
      numericString = "29103674.00";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "10345.72";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "41792210E-01";
      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(numericString, styles);

      numericString = "9112E-01";
      CallTryParse(numericString, styles);

      numericString = "312E01";
      CallTryParse(numericString, styles);

      numericString = "FFC86DA1";
      CallTryParse(numericString, NumberStyles.HexNumber);

      numericString = "0x8F8C";
      CallTryParse(numericString, NumberStyles.HexNumber);
   }

   private static void CallTryParse(string stringToConvert, NumberStyles
styles)
   {
      uint number;
      bool result = UInt32.TryParse(stringToConvert, styles,
                                    CultureInfo.InvariantCulture, out
number);
      if (result)
         Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
      else
         Console.WriteLine($"Attempted conversion of '{stringToConvert}'
failed.");
   }
}
// The example displays the following output:
//       Converted '2106034' to 2106034.
//       Attempted conversion of '-10603' failed.
//       Converted '29103674.00' to 29103674.
//       Attempted conversion of '10345.72' failed.
//       Converted '41792210E-01' to 4179221.
//       Attempted conversion of '9112E-01' failed.
//       Converted '312E01' to 3120.
//       Converted 'FFC86DA1' to 4291325345.
//       Attempted conversion of '0x8F8C' failed.
```

Remarks

The TryParse(String, NumberStyles, IFormatProvider, UInt32) method is like the Parse(String, NumberStyles, IFormatProvider) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `s` is invalid and cannot be parsed successfully.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Items in square brackets ([and]) are optional. Or, if the `style` parameter includes NumberStyles.AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag. However, if the negative sign is present, `s` can only represent the value zero for the parse operation to succeed.
digits	A sequence of digits from 0 through 9.

Element	Description
,	A culture-specific group separator. The group separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
None	Decimal digits only.
AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits, or the method returns `false`.

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*. If `s` represents a number in exponential notation, it cannot have a non-zero, fractional component.
AllowLeadingWhite	The *ws* element at the start of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element before *digits*.
AllowTrailingSign	The *sign* element after *digits*.
AllowParentheses	The *sign* element in the form of parentheses enclosing a zero numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `s`, *sign* at the start of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The *ws*, *sign*, group separator (,), and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, HexNumber, that includes both white-space flags.)

> **Note**
>
> If `s` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. The `provider` parameter can be any one of the following:

- A CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- A NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- A custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

UInt32.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt32.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

C#

```
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt64(IFormatProvider).

```
C#
long IConvertible.ToInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int64

The value of the current instance, converted to an Int64.

Implements

ToInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt64(UInt32) method.

Applies to

Product	Versions

UInt32.IConvertible.ToSByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSByte(IFormatProvider).

C#

```
sbyte IConvertible.ToSByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

SByte

The value of the current instance, converted to an SByte.

Implements

ToSByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSByte(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt32.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt32.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to which to convert this UInt32 value.

provider IFormatProvider

An IFormatProvider implementation that supplies culture-specific information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt32.IConvertible.ToUInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt16(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt32.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, unchanged.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt32.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, converted to a UInt64.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt32 instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt64(UInt32) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt32.IAdditionOperators<UInt32,UInt32,UInt32>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static uint IAdditionOperators<uint,uint,uint>.operator + (uint left, uint right);
```

Parameters

`left` UInt32

The value to which `right` is added.

`right` UInt32

The value that's added to `left`.

Returns

UInt32

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IBinaryInteger<UInt32>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<uint>.TryWriteBigEndian (Span<byte> destination, out int
bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.IBinaryInteger<UInt32>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<uint>.TryWriteLittleEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

UInt32.IBitwiseOperators<UInt32,UInt32,UInt32>.BitwiseAnd Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static uint IBitwiseOperators<uint,uint,uint>.operator & (uint left, uint right);
```

Parameters

`left` UInt32

The value to `and` with `right`.

`right` UInt32

The value to `and` with `left`.

Returns

UInt32

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IBitwiseOperators<UInt32,UInt32,UInt32>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static uint IBitwiseOperators<uint,uint,uint>.operator | (uint left, uint right);
```

Parameters

`left` UInt32

The value to `or` with `right`.

`right` UInt32

The value to `or` with `left`.

Returns

UInt32

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IBitwiseOperators<UInt32,UInt32,UInt32>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static uint IBitwiseOperators<uint,uint,uint>.operator ^ (uint left, uint right);
```

Parameters

`left` UInt32

The value to xor with `right`.

`right` UInt32

The value to xor with `left`.

Returns

UInt32

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IBitwiseOperators<UInt32,UInt32,UInt32>.OnesComplementOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
static uint IBitwiseOperators<uint,uint,uint>.operator ~ (uint value);
```

Parameters

`value` UInt32

The value for which to compute the ones-complement.

Returns

UInt32

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IComparisonOperators<UInt32,UInt32,Boolean>.GreaterThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<uint,uint,bool>.operator > (uint left, uint right);
```

Parameters

`left` UInt32

The value to compare with `right`.

`right` UInt32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IComparisonOperators<UInt32,UInt32,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<uint,uint,bool>.operator >= (uint left,
uint right);
```

Parameters

`left` UInt32

The value to compare with `right`.

`right` UInt32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IComparisonOperators<UInt32,UInt32,Boolean>.LessThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<uint,uint,bool>.operator < (uint left, uint right);
```

Parameters

`left` UInt32

The value to compare with `right`.

`right` UInt32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IDivisionOperators<UInt32,UInt32,UInt32>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static uint IDivisionOperators<uint,uint,uint>.operator / (uint left, uint right);
```

Parameters

`left` UInt32

The value that `right` divides.

`right` UInt32

The value that divides `left`.

Returns

UInt32

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IEqualityOperators<UInt32,UInt32,Boolean>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<uint,uint,bool>.operator == (uint left, uint right);
```

Parameters

`left` UInt32

The value to compare with `right`.

`right` UInt32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.IEqualityOperators<UInt32,UInt32,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<uint,uint,bool>.operator != (uint left, uint right);
```

Parameters

`left` UInt32

The value to compare with `right`.

`right` UInt32

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IIncrementOperators<UInt32>.CheckedIncrement(UInt32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#

static uint IIncrementOperators<uint>.op_CheckedIncrement (uint value);
```

Parameters

`value` UInt32

The value to increment.

Returns

UInt32

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IIncrementOperators<UInt32>.Increment(UInt32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static uint IIncrementOperators<uint>.operator ++ (uint value);
```

Parameters

`value` UInt32

The value to increment.

Returns

UInt32

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IMinMaxValue<UInt32>.Max Value Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static uint System.Numerics.IMinMaxValue<System.UInt32>.MaxValue { get; }
```

Property Value

UInt32

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IMinMaxValue<UInt32>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static uint System.Numerics.IMinMaxValue<System.UInt32>.MinValue { get; }
```

Property Value

UInt32

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IModulusOperators<UInt32,UInt32,UInt32>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static uint IModulusOperators<uint,uint,uint>.operator % (uint left, uint right);
```

Parameters

`left` UInt32

The value that `right` divides.

`right` UInt32

The value that divides `left`.

Returns

UInt32

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IMultiplicativeIdentity<UInt32,UInt32>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static uint
System.Numerics.IMultiplicativeIdentity<System.UInt32,System.UInt32>.MultiplicativeIdentity { get; }
```

Property Value

UInt32

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IMultiplyOperators<UInt32,UInt32,UInt32>.CheckedMultiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static uint IMultiplyOperators<uint,uint,uint>.op_CheckedMultiply (uint
left, uint right);
```

Parameters

`left` UInt32

The value that `right` multiplies.

`right` UInt32

The value that multiplies `left`.

Returns

UInt32

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IMultiplyOperators<UInt32,UInt32,UInt32>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static uint IMultiplyOperators<uint,uint,uint>.operator * (uint left, uint right);
```

Parameters

`left` UInt32

The value that `right` multiplies.

`right` UInt32

The value that multiplies `left`.

Returns

UInt32

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumber<UInt32>.CopySign(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
static uint INumber<uint>.CopySign (uint value, uint sign);
```

Parameters

`value` UInt32

The value whose magnitude is used in the result.

`sign` UInt32

The value whose sign is used in the result.

Returns

UInt32

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumber<UInt32>.MaxNumber(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

```
C#
static uint INumber<uint>.MaxNumber (uint x, uint y);
```

Parameters

x UInt32

The value to compare with `y`.

y UInt32

The value to compare with `x`.

Returns

UInt32

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumber<UInt32>.MinNumber(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

C#

```
static uint INumber<uint>.MinNumber (uint x, uint y);
```

Parameters

x UInt32

The value to compare with `y`.

y UInt32

The value to compare with `x`.

Returns

UInt32

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.Abs(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static uint INumberBase<uint>.Abs (uint value);
```

Parameters

`value` UInt32

The value for which to get its absolute.

Returns

UInt32

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsCanonical(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<uint>.IsCanonical (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.IsComplexNumber(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

```
C#
static bool INumberBase<uint>.IsComplexNumber (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.IsFinite(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<uint>.IsFinite (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsImaginaryNumber(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<uint>.IsImaginaryNumber (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.IsInfinity(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<uint>.IsInfinity (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsInteger(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<uint>.IsInteger (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsNaN(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<uint>.IsNaN (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsNegative(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<uint>.IsNegative (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsNegativeInfinity(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

C#

```
static bool INumberBase<uint>.IsNegativeInfinity (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsNormal(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<uint>.IsNormal (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsPositive(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
static bool INumberBase<uint>.IsPositive (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.INumberBase<UInt32>.IsRealNumber(UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<uint>.IsRealNumber (uint value);
```

Parameters

`value` UInt32

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.MaxMagnitude(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static uint INumberBase<uint>.MaxMagnitude (uint x, uint y);
```

Parameters

x UInt32

The value to compare with `y`.

y UInt32

The value to compare with `x`.

Returns

UInt32

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.MinMagnitude(UInt32, UInt32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

C#

```
static uint INumberBase<uint>.MinMagnitude (uint x, uint y);
```

Parameters

x UInt32

The value to compare with `y`.

y UInt32

The value to compare with `x`.

Returns

UInt32

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.TryConvertFromChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<uint>.TryConvertFromChecked<TOther> (TOther value,
out uint result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` UInt32

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.INumberBase<UInt32>.TryConvertFromSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<uint>.TryConvertFromSaturating<TOther> (TOther
value, out uint result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` UInt32

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.INumberBase<UInt32>.TryConvertFromTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

C#

```
static bool INumberBase<uint>.TryConvertFromTruncating<TOther> (TOther
value, out uint result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

Parameters

`value` TOther

`result` UInt32

Returns

Boolean

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.INumberBase<UInt32>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<uint>.TryConvertToChecked<TOther> (uint value, out
TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt32

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<uint>.TryConvertToSaturating<TOther> (uint value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt32

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.INumberBase<UInt32>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<uint>.TryConvertToTruncating<TOther> (uint value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt32

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.INumberBase<UInt32>.Zero Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `0` for the type.

```
C#
static uint System.Numerics.INumberBase<System.UInt32>.Zero { get; }
```

Property Value

UInt32

Implements

Zero

Applies to

Product	Versions
.NET	7, 8, 9

UInt32.IShift Operators<UInt32,Int32,UInt32>.Left Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static uint IShiftOperators<uint,int,uint>.operator << (uint value, int
shiftAmount);
```

Parameters

`value` UInt32

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

UInt32

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IShift Operators<UInt32,Int32,UInt32>.Right Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static uint IShiftOperators<uint,int,uint>.operator >> (uint value, int
shiftAmount);
```

Parameters

`value` UInt32

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt32

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IShift Operators<UInt32,Int32,UInt32>.UnsignedRightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

C#

```
static uint IShiftOperators<uint,int,uint>.op_UnsignedRightShift (uint
value, int shiftAmount);
```

Parameters

`value` UInt32

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt32

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.ISubtractionOperators<UInt32,UInt32,UInt32>.CheckedSubtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static uint ISubtractionOperators<uint,uint,uint>.op_CheckedSubtraction
(uint left, uint right);
```

Parameters

`left` UInt32

The value from which `right` is subtracted.

`right` UInt32

The value that's subtracted from `left`.

Returns

UInt32

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.ISubtractionOperators<UInt32,UInt32,UInt32>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static uint ISubtractionOperators<uint,uint,uint>.operator - (uint left,
uint right);
```

Parameters

`left` UInt32

The value from which `right` is subtracted.

`right` UInt32

The value that's subtracted from `left`.

Returns

UInt32

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt32.IUnaryNegationOperators<UInt32,UInt32>.CheckedUnaryNegation Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static uint IUnaryNegationOperators<uint,uint>.op_CheckedUnaryNegation (uint
value);
```

Parameters

`value` UInt32

The value for which to compute the unary negation.

Returns

UInt32

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IUnaryNegationOperators<UInt32,UInt32>.UnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static uint IUnaryNegationOperators<uint,uint>.operator - (uint value);
```

Parameters

`value` UInt32

The value for which to compute the unary negation.

Returns

UInt32

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt32.IUnaryPlusOperators<UInt32,UInt32>.UnaryPlus(UInt32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static uint IUnaryPlusOperators<uint,uint>.operator + (uint value);
```

Parameters

`value` UInt32

The value for which to compute the unary plus.

Returns

UInt32

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IUnsignedNumber<UInt64> , IUtf8SpanFormattable ,

IUtf8SpanParsable<UInt64> , IUtf8SpanParsable<TSelf>

Remarks

The UInt64 value type represents unsigned integers with values ranging from 0 to 18,446,744,073,709,551,615.

> **Important**
>
> The **UInt64** type is not CLS-compliant. The CLS-compliant alternative type is **Decimal**. **Int64** can be used instead to replace a **UInt64** value that ranges from zero to **MaxValue**. For more information about CLS compliance, see **Language Independence and Language-Independent Components**.

UInt64 provides methods to compare instances of this type, convert the value of an instance to its string representation, and convert the string representation of a number to an instance of this type.

Fields

Expand table

MaxValue	Represents the largest possible value of UInt64. This field is constant.
MinValue	Represents the smallest possible value of UInt64. This field is constant.

Methods

Expand table

Clamp(UInt64, UInt64, UInt64)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CompareTo(UInt64)	Compares this instance to a specified 64-bit unsigned integer and returns an indication of their relative values.

CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(UInt64, UInt64)	Computes the quotient and remainder of two values.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UInt64)	Returns a value indicating whether this instance is equal to a specified UInt64 value.
GetHashCode()	Returns the hash code for this instance.
GetTypeCode()	Returns the TypeCode for value type UInt64.
IsEvenInteger(UInt64)	Determines if a value represents an even integral number.
IsOddInteger(UInt64)	Determines if a value represents an odd integral number.
IsPow2(UInt64)	Determines if a value is a power of two.
LeadingZeroCount(UInt64)	Computes the number of leading zeros in a value.
Log2(UInt64)	Computes the log2 of a value.
Max(UInt64, UInt64)	Compares two values to compute which is greater.
Min(UInt64, UInt64)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent.
Parse(String)	Converts the string representation of a number to its 64-bit

	unsigned integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 64-bit unsigned integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 64-bit unsigned integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent.
PopCount(UInt64)	Computes the number of bits that are set in a value.
RotateLeft(UInt64, Int32)	Rotates a value left by a given amount.
RotateRight(UInt64, Int32)	Rotates a value right by a given amount.
Sign(UInt64)	Computes the sign of a value.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
TrailingZeroCount(UInt64)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current unsigned long number instance into the provided span of characters.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt64)	Tries to parse a span of UTF-8 characters into a value.

TryParse(ReadOnlySpan<Byte>, UInt64)	Tries to convert a UTF-8 character span containing the string representation of a number to its 64-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt64)	Tries to parse a span of characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt64)	Tries to convert the span representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, UInt64)	Tries to convert the span representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, IFormatProvider, UInt64)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, UInt64)	Tries to convert the string representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, UInt64)	Tries to convert the string representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

Explicit Interface Implementations

Expand table

IAdditionOperators<UInt64,UInt64,UInt64>.Addition(UInt64, UInt64)	Adds two values together to compute their sum.
IAdditionOperators<UInt64,UInt64,UInt64>.CheckedAddition(UInt64, UInt64)	Adds two values together to compute their sum.
IAdditiveIdentity<UInt64,UInt64>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<UInt64>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<UInt64>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement

	representation of the current value.
IBinaryInteger<UInt64>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, UInt64)	
IBinaryInteger<UInt64>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, UInt64)	
IBinaryInteger<UInt64>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<UInt64>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.
IBinaryNumber<UInt64>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<UInt64,UInt64,UInt64>.BitwiseAnd(UInt64, UInt64)	Computes the bitwise-and of two values.
IBitwiseOperators<UInt64,UInt64,UInt64>.BitwiseOr(UInt64, UInt64)	Computes the bitwise-or of two values.
IBitwiseOperators<UInt64,UInt64,UInt64>.ExclusiveOr(UInt64, UInt64)	Computes the exclusive-or of two values.
IBitwiseOperators<UInt64,UInt64,UInt64>.OnesComplement(UInt64)	Computes the ones-complement representation of a given value.
IComparisonOperators<UInt64,UInt64,Boolean>.GreaterThan(UInt64, UInt64)	Compares two values to determine which is greater.
IComparisonOperators<UInt64,UInt64,Boolean>.GreaterThanOrEqual(UInt64, UInt64)	Compares two values to determine which is greater or equal.
IComparisonOperators<UInt64,UInt64,Boolean>.LessThan(UInt64, UInt64)	Compares two values to determine which is less.
IComparisonOperators<UInt64,UInt64,Boolean>.LessThanOrEqual(UInt64, UInt64)	Compares two values to determine which is less or equal.
IConvertible.ToBoolean(IFormatProvider)	For a description of this member, see ToBoolean(IFormatProvider).
IConvertible.ToByte(IFormatProvider)	For a description of this member, see ToByte(IFormatProvider).
IConvertible.ToChar(IFormatProvider)	For a description of this member, see ToChar(IFormatProvider).
IConvertible.ToDateTime(IFormatProvider)	This conversion is not supported. Attempting to use this method throws an InvalidCastException.

IConvertible.ToDecimal(IFormatProvider)	For a description of this member, see ToDecimal(IFormatProvider).
IConvertible.ToDouble(IFormatProvider)	For a description of this member, see ToDouble(IFormatProvider).
IConvertible.ToInt16(IFormatProvider)	For a description of this member, see ToInt16(IFormatProvider).
IConvertible.ToInt32(IFormatProvider)	For a description of this member, see ToInt32(IFormatProvider).
IConvertible.ToInt64(IFormatProvider)	For a description of this member, see ToInt64(IFormatProvider).
IConvertible.ToSByte(IFormatProvider)	For a description of this member, see ToSByte(IFormatProvider).
IConvertible.ToSingle(IFormatProvider)	For a description of this member, see ToSingle(IFormatProvider).
IConvertible.ToType(Type, IFormatProvider)	For a description of this member, see ToType(Type, IFormatProvider).
IConvertible.ToUInt16(IFormatProvider)	For a description of this member, see ToUInt16(IFormatProvider).
IConvertible.ToUInt32(IFormatProvider)	For a description of this member, see ToUInt32(IFormatProvider).
IConvertible.ToUInt64(IFormatProvider)	For a description of this member, see ToUInt64(IFormatProvider).
IDecrementOperators<UInt64>.CheckedDecrement(UInt64)	Decrements a value.
IDecrementOperators<UInt64>.Decrement(UInt64)	Decrements a value.
IDivisionOperators<UInt64,UInt64,UInt64>.Division(UInt64, UInt64)	Divides one value by another to compute their quotient.
IEquality Operators<UInt64,UInt64,Boolean>.Equality(UInt64, UInt64)	Compares two values to determine equality.
IEquality Operators<UInt64,UInt64,Boolean>.Inequality(UInt64, UInt64)	Compares two values to determine inequality.
IIncrementOperators<UInt64>.CheckedIncrement(UInt64)	Increments a value.
IIncrementOperators<UInt64>.Increment(UInt64)	Increments a value.

IMinMaxValue<UInt64>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<UInt64>.MinValue	Gets the minimum value of the current type.
IModulus Operators<UInt64,UInt64,UInt64>.Modulus(UInt64, UInt64)	Divides two values together to compute their modulus or remainder.
IMultiplicativeIdentity<UInt64,UInt64>.Multiplicative Identity	Gets the multiplicative identity of the current type.
IMultiplyOperators<UInt64,UInt64,UInt64>.Checked Multiply(UInt64, UInt64)	Multiplies two values together to compute their product.
IMultiplyOperators<UInt64,UInt64,UInt64>.Multiply(UInt64, UInt64)	Multiplies two values together to compute their product.
INumber<UInt64>.CopySign(UInt64, UInt64)	Copies the sign of a value to the sign of another value.
INumber<UInt64>.MaxNumber(UInt64, UInt64)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<UInt64>.MinNumber(UInt64, UInt64)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<UInt64>.Abs(UInt64)	Computes the absolute of a value.
INumberBase<UInt64>.IsCanonical(UInt64)	Determines if a value is in its canonical representation.
INumberBase<UInt64>.IsComplexNumber(UInt64)	Determines if a value represents a complex number.
INumberBase<UInt64>.IsFinite(UInt64)	Determines if a value is finite.
INumberBase<UInt64>.IsImaginaryNumber(UInt64)	Determines if a value represents a pure imaginary number.
INumberBase<UInt64>.IsInfinity(UInt64)	Determines if a value is infinite.
INumberBase<UInt64>.IsInteger(UInt64)	Determines if a value represents an integral number.
INumberBase<UInt64>.IsNaN(UInt64)	Determines if a value is NaN.
INumberBase<UInt64>.IsNegative(UInt64)	Determines if a value is negative.

INumberBase<UInt64>.IsNegativeInfinity(UInt64)	Determines if a value is negative infinity.
INumberBase<UInt64>.IsNormal(UInt64)	Determines if a value is normal.
INumberBase<UInt64>.IsPositive(UInt64)	Determines if a value is positive.
INumberBase<UInt64>.IsPositiveInfinity(UInt64)	Determines if a value is positive infinity.
INumberBase<UInt64>.IsRealNumber(UInt64)	Determines if a value represents a real number.
INumberBase<UInt64>.IsSubnormal(UInt64)	Determines if a value is subnormal.
INumberBase<UInt64>.IsZero(UInt64)	Determines if a value is zero.
INumberBase<UInt64>.MaxMagnitude(UInt64, UInt64)	Compares two values to compute which is greater.
INumberBase<UInt64>.MaxMagnitudeNumber(UInt64, UInt64)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt64>.MinMagnitude(UInt64, UInt64)	Compares two values to compute which is lesser.
INumberBase<UInt64>.MinMagnitudeNumber(UInt64, UInt64)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<UInt64>.One	Gets the value `1` for the type.
INumberBase<UInt64>.Radix	Gets the radix, or base, for the type.
INumberBase<UInt64>.TryConvertFromChecked<TOther>(TOther, UInt64)	
INumberBase<UInt64>.TryConvertFromSaturating<TOther>(TOther, UInt64)	
INumberBase<UInt64>.TryConvertFromTruncating<TOther>(TOther, UInt64)	
INumberBase<UInt64>.TryConvertToChecked<TOther>(UInt64, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<UInt64>.TryConvertToSaturating<TOther>(UInt64, TOther)	Tries to convert an instance of the the current type to another type,

	saturating any values that fall outside the representable range of the current type.
INumberBase<UInt64>.TryConvertToTruncating<TOther>(UInt64, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<UInt64>.Zero	Gets the value `0` for the type.
IShiftOperators<UInt64,Int32,UInt64>.LeftShift(UInt64, Int32)	Shifts a value left by a given amount.
IShiftOperators<UInt64,Int32,UInt64>.RightShift(UInt64, Int32)	Shifts a value right by a given amount.
IShiftOperators<UInt64,Int32,UInt64>.UnsignedRightShift(UInt64, Int32)	Shifts a value right by a given amount.
ISubtractionOperators<UInt64,UInt64,UInt64>.CheckedSubtraction(UInt64, UInt64)	Subtracts two values to compute their difference.
ISubtractionOperators<UInt64,UInt64,UInt64>.Subtraction(UInt64, UInt64)	Subtracts two values to compute their difference.
IUnaryNegationOperators<UInt64,UInt64>.CheckedUnaryNegation(UInt64)	Computes the checked unary negation of a value.
IUnaryNegationOperators<UInt64,UInt64>.UnaryNegation(UInt64)	Computes the unary negation of a value.
IUnaryPlusOperators<UInt64,UInt64>.UnaryPlus(UInt64)	Computes the unary plus of a value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UWP	10.0

Thread Safety

All members of this type are thread safe. Members that appear to modify instance state actually return a new instance initialized with the new value. As with any other type, reading and writing to a shared variable that contains an instance of this type must be protected by a lock to guarantee thread safety.

UInt64.MaxValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of UInt64. This field is constant.

C#

```
public const ulong MaxValue = 18446744073709551615;
```

Field Value

Value* = *18446744073709551615

UInt64

Examples

The following example uses the MinValue and MaxValue fields to verify that a Double value is within the range of the UInt64 type before it performs a type conversion. This prevents an OverflowException at run time.

C#

```
double decimalValue = -1.5;
ulong integerValue;

// Discard fractional portion of Double value
double decimalInteger = Math.Floor(decimalValue);

if (decimalInteger <= ulong.MaxValue &&
    decimalInteger >= ulong.MinValue)
{
   integerValue = (ulong) decimalValue;
   Console.WriteLine("Converted {0} to {1}.", decimalValue, integerValue);
}
else
{
   ulong rangeLimit;
   string relationship;
```

```
    if (decimalInteger > ulong.MaxValue)
    {
       rangeLimit = ulong.MaxValue;
       relationship = "greater";
    }
    else
    {
       rangeLimit = ulong.MinValue;
       relationship = "less";
    }

    Console.WriteLine("Conversion failure: {0} is {1} than {2}.",
                      decimalInteger,
                      relationship,
                      rangeLimit);
 }
```

Remarks

The value of this constant is 18,446,744,073,709,551,615; that is, hexadecimal 0xFFFFFFFFFFFFFFFF.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.MinValue Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the smallest possible value of UInt64. This field is constant.

C#

```
public const ulong MinValue = 0;
```

Field Value

Value* = *0

UInt64

Examples

The following example uses the MinValue and MaxValue fields to verify that a Double value is within the range of the UInt64 type before it performs a type conversion. This prevents an OverflowException at run time.

C#

```
double decimalValue = -1.5;
ulong integerValue;

// Discard fractional portion of Double value
double decimalInteger = Math.Floor(decimalValue);

if (decimalInteger <= ulong.MaxValue &&
    decimalInteger >= ulong.MinValue)
{
   integerValue = (ulong) decimalValue;
   Console.WriteLine("Converted {0} to {1}.", decimalValue, integerValue);
}
else
{
   ulong rangeLimit;
   string relationship;
```

```
    if (decimalInteger > ulong.MaxValue)
    {
       rangeLimit = ulong.MaxValue;
       relationship = "greater";
    }
    else
    {
       rangeLimit = ulong.MinValue;
       relationship = "less";
    }

    Console.WriteLine("Conversion failure: {0} is {1} than {2}.",
                      decimalInteger,
                      relationship,
                      rangeLimit);
 }
```

Remarks

The value of this constant is 0.

UInt64.Clamp(UInt64, UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

```
C#
public static ulong Clamp (ulong value, ulong min, ulong max);
```

Parameters

`value` UInt64

The value to clamp.

`min` UInt64

The inclusive minimum to which `value` should clamp.

`max` UInt64

The inclusive maximum to which `value` should clamp.

Returns

UInt64

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this instance to a specified object or UInt64 and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Object)	Compares this instance to a specified object and returns an indication of their relative values.
CompareTo(UInt64)	Compares this instance to a specified 64-bit unsigned integer and returns an indication of their relative values.

CompareTo(Object)

Compares this instance to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`, or `value` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`value` is not a UInt64.

Examples

The following code example demonstrates the CompareTo method.

C#

```
public class Temperature : IComparable {
    /// <summary>
    /// IComparable.CompareTo implementation.
    /// </summary>
    public int CompareTo(object obj) {
        if(obj is Temperature) {
            Temperature temp = (Temperature) obj;

            return m_value.CompareTo(temp.m_value);
        }

        throw new ArgumentException("object is not a Temperature");
    }

    // The value holder
    protected ulong m_value;

    public ulong Value {
        get {
            return m_value;
        }
```

```
        set {
            m_value = value;
        }
    }
}
```

Remarks

Any instance of UInt64, regardless of its value, is considered greater than `null`.

`value` must be `null` or an instance of UInt64; otherwise, an exception is thrown.

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

CompareTo(UInt64)

Compares this instance to a specified 64-bit unsigned integer and returns an indication of their relative values.

C#

```
public int CompareTo (ulong value);
```

Parameters

`value` UInt64

An unsigned integer to compare.

Returns

Int32

A signed number indicating the relative values of this instance and `value`.

Expand table

Return Value	Description
Less than zero	This instance is less than `value`.
Zero	This instance is equal to `value`.
Greater than zero	This instance is greater than `value`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the CompareTo method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
```

```
of the
CompareTo method for several base types:

Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface and performs slightly better than the UInt64.CompareTo method because it does not have to convert the `value` parameter to an object.

Depending on your programming language, it might be possible to code a CompareTo method where the parameter type has fewer bits (is narrower) than the instance type. This is possible because some programming languages perform an implicit widening conversion that represents the parameter as a type with as many bits as the instance.

For example, suppose the instance type is Int32 and the parameter type is Byte. The Microsoft C# compiler generates instructions to represent the value of the parameter as an Int32 object, then generates a Int32.CompareTo method that compares the values of the Int32 instance and the Int32 parameter representation.

Consult your programming language's documentation to determine whether its compiler performs implicit widening conversions on numeric types.

UInt64.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
public static ulong CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt64

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

C#

```
public static ulong CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt64

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

C#

```
public static ulong CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UInt64

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.DivRem(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (ulong Quotient, ulong Remainder) DivRem (ulong left, ulong
right);
```

Parameters

`left` UInt64

The value which `right` divides.

`right` UInt64

The value which divides `left`.

Returns

ValueTuple<UInt64,UInt64>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether this instance is equal to a specified object or UInt64.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UInt64)	Returns a value indicating whether this instance is equal to a specified UInt64 value.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare to this instance.

Returns

Boolean

`true` if `obj` is an instance of UInt64 and equals the value of this instance; otherwise, `false`.

Examples

The following example demonstrates the Equals method.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      object[] values = { (short) 10, (short) 20, 10, 20,
                          10L, 20L, 10D, 20D, (ushort) 10,
                          (ushort) 20, 10U, 20U,
                          10ul, 20ul };
      UInt64 baseValue = 20;
      String baseType = baseValue.GetType().Name;

      foreach (var value in values)
         Console.WriteLine("{0} ({1}) = {2} ({3}): {4}",
                           baseValue, baseType,
                           value, value.GetType().Name,
                           baseValue.Equals(value));
   }
}
// The example displays the following output:
//       20 (UInt64) = 10 (Int16): False
//       20 (UInt64) = 20 (Int16): False
//       20 (UInt64) = 10 (Int32): False
//       20 (UInt64) = 20 (Int32): False
//       20 (UInt64) = 10 (Int64): False
//       20 (UInt64) = 20 (Int64): False
//       20 (UInt64) = 10 (Double): False
//       20 (UInt64) = 20 (Double): False
//       20 (UInt64) = 10 (UInt16): False
//       20 (UInt64) = 20 (UInt16): False
//       20 (UInt64) = 10 (UInt32): False
//       20 (UInt64) = 20 (UInt32): False
//       20 (UInt64) = 10 (UInt64): False
//       20 (UInt64) = 20 (UInt64): True
```

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(UInt64) method overloads. If an implicit conversion between the `obj` argument and a UInt64 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(UInt64) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj`

argument is not a UInt64 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte, UInt16, and UInt32 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(UInt64) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static ulong value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
      TestObjectForEquality(byte1);

      short short1 = 112;
      Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
      TestObjectForEquality(short1);

      int int1 = 112;
      Console.WriteLine("value = int1: {0,19}", value.Equals(int1));
      TestObjectForEquality(int1);

      sbyte sbyte1 = 112;
      Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
      TestObjectForEquality(sbyte1);

      ushort ushort1 = 112;
      Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
      TestObjectForEquality(ushort1);

      uint uint1 = 112;
      Console.WriteLine("value = uint1: {0,18}", value.Equals(uint1));
      TestObjectForEquality(uint1);

      decimal dec1 = 112m;
      Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
      TestObjectForEquality(dec1);

      double dbl1 = 112;
      Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
      TestObjectForEquality(dbl1);
   }

   private static void TestObjectForEquality(Object obj)
```

```
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (UInt64) = 112 (Byte): False
//
//       value = short1:             False
//       112 (UInt64) = 112 (Int16): False
//
//       value = int1:               False
//       112 (UInt64) = 112 (Int32): False
//
//       value = sbyte1:             False
//       112 (UInt64) = 112 (SByte): False
//
//       value = ushort1:             True
//       112 (UInt64) = 112 (UInt16): False
//
//       value = uint1:               True
//       112 (UInt64) = 112 (UInt32): False
//
//       value = dec1:                 False
//       112 (UInt64) = 112 (Decimal): False
//
//       value = dbl1:                False
//       112 (UInt64) = 112 (Double): False
```

Equals(UInt64)

Returns a value indicating whether this instance is equal to a specified UInt64 value.

C#

```
public bool Equals (ulong obj);
```

Parameters

obj UInt64

A UInt64 value to compare to this instance.

Returns

Boolean

`true` if `obj` has the same value as this instance; otherwise, `false`.

Implements

Equals(T)

Examples

The following example demonstrates the Equals method.

C#

```
using System;

class Example
{
     public static void Main()
     {
         UInt64 value1 = 50;
         UInt64 value2 = 50;

         // Display the values.
        Console.WriteLine("value1:   Type: {0}   Value: {1}",
```

```
                                value1.GetType().Name, value1);
        Console.WriteLine("value2:   Type: {0}   Value: {1}",
                                value2.GetType().Name, value2);

        // Compare the two values.
        Console.WriteLine("value1 and value2 are equal: {0}",
                                value1.Equals(value2));
    }
}
// The example displays the following output:
//       value1:   Type: UInt64   Value: 50
//       value2:   Type: UInt64   Value: 50
//       value1 and value2 are equal: True
```

Remarks

This method implements the System.IEquatable<T> interface, and performs slightly better than Equals because it does not have to convert the `obj` parameter to an object.

Notes to Callers

Compiler overload resolution may account for an apparent difference in the behavior of the two Equals(UInt64) method overloads. If an implicit conversion between the `obj` argument and a UInt64 is defined and the argument is not typed as an Object, compilers perform an implicit conversion and call the Equals(UInt64) method. Otherwise, they call the Equals(Object) method, which always returns `false` if its `obj` argument is not a UInt64 value. The following example illustrates the difference in behavior between the two method overloads. In the case of the Byte, UInt16, and UInt32 values, the first comparison returns `true` because the compiler automatically performs a widening conversion and calls the Equals(UInt64) method, whereas the second comparison returns `false` because the compiler calls the Equals(Object) method.

C#

```
using System;

public class Example
{
   static ulong value = 112;

   public static void Main()
   {
      byte byte1= 112;
      Console.WriteLine("value = byte1: {0,16}", value.Equals(byte1));
```

```
        TestObjectForEquality(byte1);

        short short1 = 112;
        Console.WriteLine("value = short1: {0,17}", value.Equals(short1));
        TestObjectForEquality(short1);

        int int1 = 112;
        Console.WriteLine("value = int1: {0,19}", value.Equals(int1));
        TestObjectForEquality(int1);

        sbyte sbyte1 = 112;
        Console.WriteLine("value = sbyte1: {0,17}", value.Equals(sbyte1));
        TestObjectForEquality(sbyte1);

        ushort ushort1 = 112;
        Console.WriteLine("value = ushort1: {0,16}",
value.Equals(ushort1));
        TestObjectForEquality(ushort1);

        uint uint1 = 112;
        Console.WriteLine("value = uint1: {0,18}", value.Equals(uint1));
        TestObjectForEquality(uint1);

        decimal dec1 = 112m;
        Console.WriteLine("value = dec1: {0,21}", value.Equals(dec1));
        TestObjectForEquality(dec1);

        double dbl1 = 112;
        Console.WriteLine("value = dbl1: {0,20}", value.Equals(dbl1));
        TestObjectForEquality(dbl1);
    }

    private static void TestObjectForEquality(Object obj)
    {
        Console.WriteLine("{0} ({1}) = {2} ({3}): {4}\n",
                          value, value.GetType().Name,
                          obj, obj.GetType().Name,
                          value.Equals(obj));
    }
}
// The example displays the following output:
//       value = byte1:             True
//       112 (UInt64) = 112 (Byte): False
//
//       value = short1:             False
//       112 (UInt64) = 112 (Int16): False
//
//       value = int1:               False
//       112 (UInt64) = 112 (Int32): False
//
//       value = sbyte1:             False
//       112 (UInt64) = 112 (SByte): False
//
//       value = ushort1:             True
//       112 (UInt64) = 112 (UInt16): False
```

```
//
//       value = uint1:                True
//       112 (UInt64) = 112 (UInt32): False
//
//       value = dec1:                  False
//       112 (UInt64) = 112 (Decimal): False
//
//       value = dbl1:                 False
//       112 (UInt64) = 112 (Double): False
```

UInt64.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.GetTypeCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the TypeCode for value type UInt64.

C#

```
public TypeCode GetTypeCode ();
```

Returns

TypeCode

The enumerated constant, UInt64.

Implements

GetTypeCode()

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt64.IsEvenInteger(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IsOddInteger(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

UInt64.IsPow2(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.LeadingZeroCount(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

C#

```
public static ulong LeadingZeroCount (ulong value);
```

Parameters

`value` UInt64

The value whose leading zeroes are to be counted.

Returns

UInt64

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.Log2(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

C#

```
public static ulong Log2 (ulong value);
```

Parameters

`value` UInt64

The value whose log2 is to be computed.

Returns

UInt64

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.Max(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static ulong Max (ulong x, ulong y);
```

Parameters

x UInt64

The value to compare with `y`.

y UInt64

The value to compare with `x`.

Returns

UInt64

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

UInt64.Min(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static ulong Min (ulong x, ulong y);
```

Parameters

x UInt64

The value to compare with `y`.

y UInt64

The value to compare with `x`.

Returns

UInt64

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the string representation of a number to its 64-bit unsigned integer equivalent.

Overloads

Expand table

Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the span representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its 64-bit unsigned integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its 64-bit unsigned integer equivalent.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(String)	Converts the string representation of a number to its 64-bit unsigned integer equivalent.

Parse(String, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.Parse(String)**

Converts the string representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent.

C#

```
public static ulong Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt64

A 64-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

The `s` parameter is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

The `s` parameter is not in a format compliant with `style`.

OverflowException

The `s` parameter represents a number less than UInt64.MinValue or greater than UInt64.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example uses the Parse(String, NumberStyles, IFormatProvider) method to convert various string representations of numbers to 64-bit unsigned integer values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] cultureNames= { "en-US", "fr-FR" };
      NumberStyles[] styles= { NumberStyles.Integer,
                               NumberStyles.Integer |
NumberStyles.AllowDecimalPoint };
      string[] values = { "170209", "+170209.0", "+170209,0",
"-103214.00",
                                  "-103214,00", "104561.1", "104561,1" };

      // Parse strings using each culture
      foreach (string cultureName in cultureNames)
      {
         CultureInfo ci = new CultureInfo(cultureName);
         Console.WriteLine("Parsing strings using the {0} culture",
                           ci.DisplayName);
         // Use each style.
```

```
         foreach (NumberStyles style in styles)
         {
            Console.WriteLine("   Style: {0}", style.ToString());
            // Parse each numeric string.
            foreach (string value in values)
            {
               try {
                  Console.WriteLine("      Converted '{0}' to {1}.",
value,
                                    UInt64.Parse(value, style, ci));
               }
               catch (FormatException) {
                  Console.WriteLine("      Unable to parse '{0}'.",
value);
               }
               catch (OverflowException) {
                  Console.WriteLine("      '{0}' is out of range of the
UInt64 type.",
                                    value);
               }
            }
         }
      }
   }
}
// The example displays the following output:
//       Style: Integer
//          Converted '170209' to 170209.
//          Unable to parse '+170209.0'.
//          Unable to parse '+170209,0'.
//          Unable to parse '-103214.00'.
//          Unable to parse '-103214,00'.
//          Unable to parse '104561.1'.
//          Unable to parse '104561,1'.
//       Style: Integer, AllowDecimalPoint
//          Converted '170209' to 170209.
//          Converted '+170209.0' to 170209.
//          Unable to parse '+170209,0'.
//          '-103214.00' is out of range of the UInt64 type.
//          Unable to parse '-103214,00'.
//          '104561.1' is out of range of the UInt64 type.
//          Unable to parse '104561,1'.
//    Parsing strings using the French (France) culture
//       Style: Integer
//          Converted '170209' to 170209.
//          Unable to parse '+170209.0'.
//          Unable to parse '+170209,0'.
//          Unable to parse '-103214.00'.
//          Unable to parse '-103214,00'.
//          Unable to parse '104561.1'.
//          Unable to parse '104561,1'.
//       Style: Integer, AllowDecimalPoint
//          Converted '170209' to 170209.
//          Unable to parse '+170209.0'.
//          Converted '+170209,0' to 170209.
```

```
//          Unable to parse '-103214.00'.
//          '-103214,00' is out of range of the UInt64 type.
//          Unable to parse '104561.1'.
//          '104561,1' is out of range of the UInt64 type.
```

Remarks

The `style` parameter defines the style elements (such as white space or the positive or negative sign symbol) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Elements in square brackets ([and]) are optional. If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object that is returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. (The method throws an OverflowException if `s` includes a negative sign and represents a non-zero number.) The sign can appear at the beginning of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can

Element	Description
	be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag.
digits	A sequence of digits from 0 through 9.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0-9 if `style` includes the NumberStyles.AllowExponent flag, or one or more occurrences of the digit 0 if it does not. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None style) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
NumberStyles.None	Decimal digits only.
NumberStyles.AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, if style does not include the

Non-composite `NumberStyles` values	Elements permitted in `s` in addition to digits
	NumberStyles.AllowExponent flag, *fractional_digits* must consist of only one or more 0 digits; otherwise, an OverflowException is thrown.
NumberStyles.AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
NumberStyles.AllowLeadingWhite	The *ws* element at the beginning of `s`.
NumberStyles.AllowTrailingWhite	The *ws* element at the end of `s`.
NumberStyles.AllowLeadingSign	A sign before *digits*.
NumberStyles.AllowTrailingSign	A sign after *digits*.
NumberStyles.AllowParentheses	Parentheses before and after *digits* to indicate a negative value.
NumberStyles.AllowThousands	The group separator (,) element.
NumberStyles.AllowCurrencySymbol	The currency ($) element.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. Valid hexadecimal characters are 0-9, A-F, and a-f. A prefix such as "0x" is not supported and causes the parse operation to fail. The only other flags that can be combined with it are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

> **Note**
>
> If the `s` parameter is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the parse operation to throw an exception.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.
- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

> Important
>
> This API is not CLS-compliant.

Converts the span representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent.

```C#
public static ulong Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt64

A 64-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static ulong Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt64

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String, IFormatProvider)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.Parse(String)**

Converts the string representation of a number in a specified culture-specific format to its 64-bit unsigned integer equivalent.

```
C#
public static ulong Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string that represents the number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UInt64

A 64-bit unsigned integer equivalent to the number specified in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

The `s` parameter is `null`.

FormatException

The `s` parameter is not in the correct style.

OverflowException

The `s` parameter represents a number less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example is the button click event handler of a Web form. It uses the array returned by the HttpRequest.UserLanguages property to determine the user's locale. It then instantiates a CultureInfo object that corresponds to that locale. The NumberFormatInfo object that belongs to that CultureInfo object is then passed to the Parse(String, IFormatProvider) method to convert the user's input to a UInt64 value.

C#

```
protected void OkToSingle_Click(object sender, EventArgs e)
{
    string locale;
    float number;
    CultureInfo culture;

    // Return if string is empty
    if (String.IsNullOrEmpty(this.inputNumber.Text))
        return;

    // Get locale of web request to determine possible format of number
    if (Request.UserLanguages.Length == 0)
        return;
    locale = Request.UserLanguages[0];
    if (String.IsNullOrEmpty(locale))
        return;

    // Instantiate CultureInfo object for the user's locale
    culture = new CultureInfo(locale);

    // Convert user input from a string to a number
    try
    {
        number = Single.Parse(this.inputNumber.Text,
culture.NumberFormat);
    }
    catch (FormatException)
    {
        return;
    }
    catch (Exception)
    {
        return;
    }
    // Output number to label on web form
```

```
    this.outputNumber.Text = "Number is " + number.ToString();
}
```

Remarks

This overload of the Parse(String, IFormatProvider) method is typically used to convert text that can be formatted in a variety of ways to a UInt64 value. For example, it can be used to convert the text entered by a user into an HTML text box to a numeric value.

The `s` parameter contains a number of the form:

[ws][sign]digits[ws]

Items in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional positive sign, or a negative sign if `s` represents the value zero.
digits	A sequence of digits ranging from 0 to 9.

The s parameter is interpreted using the NumberStyles.Integer style. In addition to the unsigned integer value's decimal digits, only leading and trailing spaces along with a leading sign is allowed. (If the negative sign is present, `s` must represent a value of zero, or the method throws an OverflowException.) To explicitly define the style elements together with the culture-specific formatting information that can be present in `s`, use the Parse(String, NumberStyles, IFormatProvider) method.

The `provider` parameter is an IFormatProvider implementation whose GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. There are three ways to use the `provider` parameter to supply custom formatting information to the parse operation:

- You can pass the actual NumberFormatInfo object that provides formatting information. (Its implementation of GetFormat simply returns itself.)
- You can pass a CultureInfo object that specifies the culture whose formatting is to be used. Its NumberFormat property provides formatting information.

- You can pass a custom IFormatProvider implementation. Its GetFormat method must instantiate and return the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo for the current culture is used.

Parse(String, NumberStyles)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.Parse(String)**

Converts the string representation of a number in a specified style to its 64-bit unsigned integer equivalent.

C#

```
public static ulong Parse (string s, System.Globalization.NumberStyles
```

```
style);
```

Parameters

s String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

style NumberStyles

A bitwise combination of the enumeration values that specifies the permitted format of `s`. A typical value to specify is Integer.

Returns

UInt64

A 64-bit unsigned integer equivalent to the number specified in `s`.

Exceptions

ArgumentNullException

The `s` parameter is `null`.

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

The `s` parameter is not in a format compliant with `style`.

OverflowException

The `s` parameter represents a number less than UInt64.MinValue or greater than UInt64.MaxValue.

-or-

`s` includes non-zero, fractional digits.

Examples

The following example tries to parse each element in a string array by using a number of NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string[] values= { " 214309 ", "1,064,181", "(0)", "10241+", " +
21499 ",
                         " +21499 ", "122153.00", "1e03ff", "91300.0e-2"
};
      NumberStyles whitespace =  NumberStyles.AllowLeadingWhite |
NumberStyles.AllowTrailingWhite;
      NumberStyles[] styles= { NumberStyles.None, whitespace,
                               NumberStyles.AllowLeadingSign |
NumberStyles.AllowTrailingSign | whitespace,
                               NumberStyles.AllowThousands |
NumberStyles.AllowCurrencySymbol,
                               NumberStyles.AllowExponent |
NumberStyles.AllowDecimalPoint };

      // Attempt to convert each number using each style combination.
      foreach (string value in values)
      {
         Console.WriteLine("Attempting to convert '{0}':", value);
         foreach (NumberStyles style in styles)
         {
            try {
               ulong number = UInt64.Parse(value, style);
               Console.WriteLine("   {0}: {1}", style, number);
            }
            catch (FormatException) {
               Console.WriteLine("   {0}: Bad Format", style);
            }
            catch (OverflowException)
            {
               Console.WriteLine("   {0}: Overflow", value);
            }
         }
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//    Attempting to convert ' 214309 ':
//       None: Bad Format
```

```
//       AllowLeadingWhite, AllowTrailingWhite: 214309
//       Integer, AllowTrailingSign: 214309
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '1,064,181':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: 1064181
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '(0)':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '10241+':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: 10241
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert ' + 21499 ':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert ' +21499 ':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format

//       AllowDecimalPoint, AllowExponent: 122153
//
//    Attempting to convert '1e03ff':
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: Bad Format
//
//    Attempting to convert '91300.0e-2':
```

```
//       None: Bad Format
//       AllowLeadingWhite, AllowTrailingWhite: Bad Format
//       Integer, AllowTrailingSign: Bad Format
//       AllowThousands, AllowCurrencySymbol: Bad Format
//       AllowDecimalPoint, AllowExponent: 913
```

Remarks

The `style` parameter defines the style elements (such as white space, the positive or negative sign symbol, the group separator symbol, or the decimal point symbol) that are allowed in the `s` parameter for the parse operation to succeed. `style` must be a combination of bit flags from the NumberStyles enumeration. The `style` parameter makes this method overload useful when `s` contains the string representation of a hexadecimal value, when the number system (decimal or hexadecimal) represented by `s` is known only at run time, or when you want to disallow white space or a sign symbol in `s`.

Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Elements in square brackets ([and]) are optional. If `style` includes NumberStyles.AllowHexSpecifier, the `s` parameter may contain the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the NumberFormatInfo.CurrencyNegativePattern and NumberFormatInfo.CurrencyPositivePattern properties of the current culture. The current culture's currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.

Element	Description
sign	An optional sign. The sign can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag. However, the negative sign symbol can be used only with zero; otherwise, the method throws an OverflowException.
digits *fractional_digits* *exponential_digits*	A sequence of digits from 0 through 9. For *fractional_digits*, only the digit 0 is valid.
,	A culture-specific group separator symbol. The current culture's group separator can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The current culture's decimal point symbol can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag. Only the digit 0 can appear as a fractional digit for the parse operation to succeed; if *fractional_digits* includes any other digit, a FormatException is thrown.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with digits only (which corresponds to the NumberStyles.None style) always parses successfully if it is in the range of the UInt64 type. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in the input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

`NumberStyles` value	Elements permitted in `s` in addition to digits
None	The *digits* element only.
AllowDecimalPoint	The decimal point (.) and *fractional-digits* elements.
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*.
AllowLeadingWhite	The *ws* element at the start of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element at the start of `s`.
AllowTrailingSign	The *sign* element at the end of `s`.
AllowParentheses	The *sign* element in the form of parentheses enclosing the numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `s`, *sign* at the start of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The `ws`, `sign`, group separator (,), and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

Unlike the other NumberStyles values, which allow for, but do not require, the presence of particular style elements in `s`, the NumberStyles.AllowHexSpecifier style value means that the individual numeric characters in `s` are always interpreted as hexadecimal characters. Valid hexadecimal characters are 0-9, A-F, and a-f. A prefix such as "0x" is not supported and causes the parse operation to fail. The only other flags that can be combined with the `style` parameter are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration includes a composite number style, NumberStyles.HexNumber, that includes both white-space flags.)

Note

If `s` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `s` parameter is parsed by using the formatting information in a NumberFormatInfo object that is initialized for the current system culture. To specify the culture whose formatting information is used for the parse operation, call the Parse(String, NumberStyles, IFormatProvider) overload.

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

C#

```
public static ulong Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UInt64

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static ulong Parse (ReadOnlySpan<byte> utf8Text, IFormatProvider?
provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UInt64

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(String)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.Parse(String)**

Converts the string representation of a number to its 64-bit unsigned integer equivalent.

C#

```
public static ulong Parse (string s);
```

Parameters

s String

A string that represents the number to convert.

Returns

UInt64

A 64-bit unsigned integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

The `s` parameter is `null`.

FormatException

The `s` parameter is not in the correct format.

OverflowException

The `s` parameter represents a number less than UInt64.MinValue or greater than UInt64.MaxValue.

Examples

The following example uses the Parse method to parse an array of string values.

C#

```
string[] values = { "+13230", "-0", "1,390,146", "$190,235,421,127",
                    "0xFA1B", "163042", "-10", "14065839182",
                    "16e07", "134985.0", "-12034" };
foreach (string value in values)
{
   try {
      ulong number = UInt64.Parse(value);
      Console.WriteLine("{0} --> {1}", value, number);
   }
   catch (FormatException) {
      Console.WriteLine("{0}: Bad Format", value);
   }
   catch (OverflowException) {
      Console.WriteLine("{0}: Overflow", value);
   }
}
// The example displays the following output:
//       +13230 --> 13230
//       -0 --> 0
//       1,390,146: Bad Format
//       $190,235,421,127: Bad Format
//       0xFA1B: Bad Format
//       163042 --> 163042
//       -10: Overflow
//       14065839182 --> 14065839182
//       16e07: Bad Format
```

```
//        134985.0: Bad Format
//        -12034: Overflow
```

Remarks

The `s` parameter should be the string representation of a number in the following form.

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture. However, the negative sign symbol can be used only with zero; otherwise, the method throws an OverflowException.
digits	A sequence of digits ranging from 0 to 9. Any leading zeros are ignored.

> **Note**
>
> The string specified by the `s` parameter is interpreted by using the **NumberStyles.Integer** style. It cannot contain any group separators or decimal separator, and it cannot have a decimal portion.

The `s` parameter is parsed by using the formatting information in a System.Globalization.NumberFormatInfo object that is initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo. To parse a string by using the formatting information of a specific culture, use the Parse(String, IFormatProvider) method.

UInt64.PopCount(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static ulong PopCount (ulong value);
```

Parameters

`value` UInt64

The value whose set bits are to be counted.

Returns

UInt64

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.RotateLeft(UInt64, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static ulong RotateLeft (ulong value, int rotateAmount);
```

Parameters

`value` UInt64

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

UInt64

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.RotateRight(UInt64, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

```
C#
public static ulong RotateRight (ulong value, int rotateAmount);
```

Parameters

`value` UInt64

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

UInt64

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.Sign(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (ulong value);
```

Parameters

`value` UInt64

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the numeric value of this instance to its equivalent string representation.

Overloads

Expand table

ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation using the specified format.
ToString(String, IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString()	Converts the numeric value of this instance to its equivalent string representation.

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

provider IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance, consisting of a sequence of digits ranging from 0 to 9, without a sign or leading zeros.

Implements

ToString(IFormatProvider)

Examples

The following example formats a 64-bit signed integer value by using several format providers, including one for the invariant culture. The output from the example illustrates that the formatted string returned by the ToString(IFormatProvider) method is the same regardless of the format provider.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define an array of CultureInfo objects.
      CultureInfo[] ci = { new CultureInfo("en-US"),
                           new CultureInfo("fr-FR"),
                           CultureInfo.InvariantCulture };
      ulong value = 18709243;
      Console.WriteLine("  {0,12}   {1,12}   {2,12}",
                        GetName(ci[0]), GetName(ci[1]), GetName(ci[2]));
      Console.WriteLine("  {0,12}   {1,12}   {2,12}",
                        value.ToString(ci[0]), value.ToString(ci[1]),
value.ToString(ci[2]));
   }

   private static string GetName(CultureInfo ci)
   {
      if (ci.Equals(CultureInfo.InvariantCulture))
         return "Invariant";
      else
         return ci.Name;
   }
}
```

```
// The example displays the following output:
//              en-US          fr-FR      Invariant
//           18709243       18709243       18709243
```

Remarks

The ToString(IFormatProvider) method formats a UInt64 value in the default ("G", or general) format by using the NumberFormatInfo object of a specified culture. If you want to specify a different format or the current culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific formatting information. However, none of the properties of the NumberFormatInfo are used when formatting with the general numeric format specifier ("G").

.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

ToString(String)

Converts the numeric value of this instance to its equivalent string representation using the specified format.

```
C#

public string ToString (string? format);
```

Parameters

`format` String

A numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

The `format` parameter is invalid.

Examples

The following example displays a 64-bit unsigned integer value by using each standard format string and some custom format strings.

```
C#

using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
```

```
        ulong value = 217960834;
        string[] specifiers = { "G", "C", "D3", "E2", "e3", "F",
                                "N", "P", "X", "000000.0", "#.0",
                                "00000000;(0);**Zero**" };

        foreach (string specifier in specifiers)
           Console.WriteLine("{0}: {1}", specifier,
value.ToString(specifier));
    }
}
// The example displays the following output:
//       G: 217960834
//       C: $217,960,834.00
//       D3: 217960834
//       E2: 2.18E+008
//       e3: 2.180e+008
//       F: 217960834.00
//       N: 217,960,834.00
//       P: 21,796,083,400.00 %
//       X: CFDD182
//       000000.0: 217960834.0
//       #.0: 217960834.0
//       00000000;(0);**Zero**: 217960834
```

Remarks

The ToString(String) method formats a UInt64 value in a specified format by using a NumberFormatInfo object that represents the conventions of the current culture. If you want to use the default ("G", or general) format or specify a different culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	A specific culture	ToString(String, IFormatProvider)

The `format` parameter can be any valid Standard Numeric Format Strings, or any combination of Custom Numeric Format Strings. If `format` is equal to String.Empty or is `null`, the return value of the current UInt64 object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about support for formatting in .NET, see Formatting Types.

The format of the returned string is determined by the NumberFormatInfo object for the current culture. Depending on the `format` parameter, this object controls symbols such as the group separator and the decimal point symbol in the output string. To provide formatting information for cultures other than the current culture, call the ToString(String, IFormatProvider) overload.

ToString(String, IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

```
C#
```

```
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

A numeric format string.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about this instance.

Returns

String

The string representation of the value of this instance as specified by `format` and `provider`.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

The `format` parameter is invalid.

Examples

The following example displays a 32-bit unsigned integer value by using the standard numeric format specifiers and a number of specific CultureInfo objects.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      // Define cultures whose formatting conventions are to be used.
      CultureInfo[] cultures = { CultureInfo.CreateSpecificCulture("en-
US"),
```

```
                                    CultureInfo.CreateSpecificCulture("fr-
FR"),
                                    CultureInfo.CreateSpecificCulture("es-
ES") };
      string[] specifiers = {"G", "C", "D4", "E2", "F", "N", "P", "X2"};
      ulong value = 22224021;

      foreach (string specifier in specifiers)
      {
         foreach (CultureInfo culture in cultures)
            Console.WriteLine("{0,2} format using {1} culture: {2, 18}",
                              specifier, culture.Name,
                              value.ToString(specifier, culture));
         Console.WriteLine();
      }
   }
}
// The example displays the following output:
//        G format using en-US culture:           22224021
//        G format using fr-FR culture:           22224021
//        G format using es-ES culture:           22224021
//
//        C format using en-US culture:     $22,224,021.00
//        C format using fr-FR culture:    22 224 021,00 €
//        C format using es-ES culture:    22.224.021,00 €
//
//       D4 format using en-US culture:           22224021
//       D4 format using fr-FR culture:           22224021
//       D4 format using es-ES culture:           22224021
//
//       E2 format using en-US culture:          2.22E+007
//       E2 format using fr-FR culture:          2,22E+007
//       E2 format using es-ES culture:          2,22E+007
//
//        F format using en-US culture:        22224021.00
//        F format using fr-FR culture:        22224021,00
//        F format using es-ES culture:        22224021,00
//
//        N format using en-US culture:      22,224,021.00
//        N format using fr-FR culture:      22 224 021,00
//        N format using es-ES culture:      22.224.021,00
//
//        P format using en-US culture: 2,222,402,100.00 %
//        P format using fr-FR culture: 2 222 402 100,00 %
//        P format using es-ES culture: 2.222.402.100,00 %
//
//       X2 format using en-US culture:            1531C95
//       X2 format using fr-FR culture:            1531C95
//       X2 format using es-ES culture:            1531C95
```

Remarks

The ToString(String, IFormatProvider) method formats a UInt64 value in a specified format by using the NumberFormatInfo object of a specified culture. If you want to use default format or culture settings, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	Default (current) culture	ToString()
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)

The `format` parameter can be any valid Standard Numeric Format Strings, or any combination of Custom Numeric Format Strings. If `format` is equal to String.Empty or is `null`, the return value of the current UInt64 object is formatted with the general format specifier ("G"). If `format` is any other value, the method throws a FormatException.

.NET provides extensive formatting support, which is described in greater detail in the following formatting topics:

- For more information about numeric format specifiers, see Standard Numeric Format Strings and Custom Numeric Format Strings.
- For more information about formatting, see Formatting Types.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of the string returned by this method. When the ToString(String, IFormatProvider) method is invoked, it calls the `provider` parameter's IFormatProvider.GetFormat method and passes it a Type object that represents the NumberFormatInfo type. The GetFormat method then returns the NumberFormatInfo object that provides information for formatting the current UInt64 value, such as the group separator symbol or the decimal point symbol. There are three ways to use the `provider` parameter to supply formatting information to the ToString(String, IFormatProvider) method:

- You can pass a CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.

- You can pass the actual NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- You can pass a custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the formatting of the returned string is based on the NumberFormatInfo object of the current culture.

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance, consisting of a sequence of digits ranging from 0 to 9, without a sign or leading zeroes.

Examples

The following example displays a UInt64 value by using the default ToString() method. It also displays the string representations of the UInt64 value that results from using some standard format specifiers. The examples are displayed using the formatting conventions of the en-US culture.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      ulong value = 163249057;
      // Display value using default ToString method.
      Console.WriteLine(value.ToString());
      Console.WriteLine();

      // Define an array of format specifiers.
      string[] formats = { "G", "C", "D", "F", "N", "X" };
      // Display value using the standard format specifiers.
      foreach (string format in formats)
         Console.WriteLine("{0} format specifier: {1,16}",
                           format, value.ToString(format));
   }
}
// The example displays the following output:
//       163249057
//
//       G format specifier:        163249057
//       C format specifier:  $163,249,057.00
//       D format specifier:        163249057
//       F format specifier:     163249057.00
//       N format specifier:   163,249,057.00
//       X format specifier:          9BAFBA1
```

Remarks

The ToString() method formats a UInt64 value in the default ("G", or general) format by using the NumberFormatInfo object of the current culture. If you want to specify a different format or culture, use the other overloads of the ToString method, as follows:

Expand table

To use format	For culture	Use the overload
Default ("G") format	A specific culture	ToString(IFormatProvider)
A specific format	Default (current) culture	ToString(String)
A specific format	A specific culture	ToString(String, IFormatProvider)

UInt64.TrailingZeroCount(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

C#

```
public static ulong TrailingZeroCount (ulong value);
```

Parameters

`value` UInt64

The value whose trailing zeroes are to be counted.

Returns

UInt64

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current unsigned long number instance into the provided span of characters.

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

utf8Destination Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

bytesWritten Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current unsigned long number instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format of `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

UInt64.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert the string representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

Overloads

Expand table

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, UInt64)	Tries to convert the span representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(String, UInt64)	Tries to convert the string representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt64)	Tries to parse a span of characters into a value.
TryParse(String, IFormatProvider, UInt64)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt64)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, UInt64)	Tries to convert a UTF-8 character span containing the string representation of a number to its 64-bit unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt64)	Tries to convert the span representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(String, NumberStyles, IFormatProvider, UInt64)	Tries to convert the string representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UInt64)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out ulong result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt64

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, UInt64)

> Important
>
> This API is not CLS-compliant.

Tries to convert the span representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (ReadOnlySpan<char> s, out ulong result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert.

`result` UInt64

When this method returns, contains the 64-bit unsigned integer value that is equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than UInt64.MinValue or greater than UInt64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, UInt64)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.Parse(String)**

Tries to convert the string representation of a number to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

```
C#
public static bool TryParse (string? s, out ulong result);
```

Parameters

`s` String

A string that represents the number to convert.

`result` UInt64

When this method returns, contains the 64-bit unsigned integer value that is equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not of the correct format, or represents a number less than UInt64.MinValue or greater than UInt64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Examples

The following example calls the TryParse(String, UInt64) method once for each element in a string array.

```
C#
```

```
string[] numericStrings = { "1293.8", "+1671.7", "28347.",
                            "   33113684  ", "(0)", "-0", "+1293617",
                            "18-", "119870", "31,024", "  3127094 ",
                            "00700000" };
ulong number;
foreach (string numericString in numericStrings)
{
   if (UInt64.TryParse(numericString, out number))
      Console.WriteLine("Converted '{0}' to {1}.", numericString,
number);
   else
      Console.WriteLine("Cannot convert '{0}' to a UInt64.",
numericString);
}
// The example displays the following output:
//       Cannot convert '1293.8' to a UInt64.
//       Cannot convert '+1671.7' to a UInt64.
//       Cannot convert '28347.' to a UInt64.
//       Converted '   33113684  ' to 33113684.
//       Cannot convert '(0)' to a UInt64.
//       Converted '-0' to 0.
//       Converted '+1293617' to 1293617.
//       Cannot convert '18-' to a UInt64.
//       Converted '119870' to 119870.
//       Cannot convert '31,024' to a UInt64.
//       Converted '  3127094 ' to 3127094.
//       Converted '0070000' to 70000.
```

Remarks

The TryParse(String, UInt64) method is like the Parse(String) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `s` is invalid and cannot be successfully parsed.

The `s` parameter should be the string representation of a decimal number in the following form:

[*ws*][*sign*]*digits*[*ws*]

Elements in square brackets ([and]) are optional. The following table describes each element.

Expand table

Element	Description
ws	Optional white space.

Element	Description
sign	An optional sign. Valid sign characters are determined by the NumberFormatInfo.NegativeSign and NumberFormatInfo.PositiveSign properties of the current culture.
digits	A sequence of decimal digits ranging from 0 to 9.

The `s` parameter is interpreted by using the NumberStyles.Integer style. In addition to the decimal digits, only leading and trailing spaces with a leading sign are allowed. To explicitly define the style elements with the culture-specific formatting information that can be present in `s`, call the TryParse(String, NumberStyles, IFormatProvider, UInt64) method.

> **Note**
>
> The string specified by the `s` parameter cannot contain any group separators or decimal separator, and it cannot have a fractional portion.

The `s` parameter is parsed using the formatting information in a NumberFormatInfo object initialized for the current system culture. For more information, see NumberFormatInfo.CurrentInfo.

This overload interprets all digits in the `s` parameter as decimal digits. To parse the string representation of a hexadecimal number, call the TryParse(String, NumberStyles, IFormatProvider, UInt64) overload instead.

TryParse(ReadOnlySpan<Char>, IFormatProvider, UInt64)

Tries to parse a span of characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out ulong result);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt64

When this method returns, contains the result of successfully parsing `s`, or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(String, IFormatProvider, UInt64)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
ulong result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UInt64

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UInt64)

Tries to parse a span of UTF-8 characters into a value.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
ulong result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UInt64

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Byte>, UInt64)

Tries to convert a UTF-8 character span containing the string representation of a number to its 64-bit unsigned integer equivalent.

```
C#

public static bool TryParse (ReadOnlySpan<byte> utf8Text, out ulong
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` UInt64

When this method returns, contains the 64-bit unsigned integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UInt64)

Important

This API is not CLS-compliant.

Tries to convert the span representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
ulong result);
```

Parameters

`s` ReadOnlySpan<Char>

A span containing the characters that represent the number to convert. The span is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UInt64

When this method returns, contains the 64-bit unsigned integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than UInt64.MinValue or greater than UInt64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryParse(String, NumberStyles, IFormatProvider, UInt64)

> Important
>
> This API is not CLS-compliant.
>
> CLS-compliant alternative **System.Decimal.Parse(String)**

Tries to convert the string representation of a number in a specified style and culture-specific format to its 64-bit unsigned integer equivalent. A return value indicates whether the conversion succeeded or failed.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out ulong result);
```

Parameters

`s` String

A string that represents the number to convert. The string is interpreted by using the style specified by the `style` parameter.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the permitted format of `s`. A typical value to specify is Integer.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UInt64

When this method returns, contains the 64-bit unsigned integer value equivalent to the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or Empty, is not in a format compliant with `style`, or represents a number less than UInt64.MinValue or greater than UInt64.MaxValue. This parameter is passed uninitialized; any value originally supplied in `result` will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Exceptions

ArgumentException

`style` is not a NumberStyles value.

-or-

`style` is not a combination of AllowHexSpecifier and HexNumber values.

Examples

The following example calls the TryParse(String, NumberStyles, IFormatProvider, UInt64) method with a number of different strings and NumberStyles values.

C#

```
using System;
using System.Globalization;

public class Example
{
   public static void Main()
   {
      string numericString;
      NumberStyles styles;

      numericString = "2106034";
      styles = NumberStyles.Integer;
      CallTryParse(numericString, styles);

      numericString = "-10603";
      styles = NumberStyles.None;
      CallTryParse(numericString, styles);
```

```
      numericString = "29103674.00";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "10345.72";
      styles = NumberStyles.Integer | NumberStyles.AllowDecimalPoint;
      CallTryParse(numericString, styles);

      numericString = "41792210E-01";
      styles = NumberStyles.Integer | NumberStyles.AllowExponent;
      CallTryParse(numericString, styles);

      numericString = "9112E-01";
      CallTryParse(numericString, styles);

      numericString = "312E01";
      CallTryParse(numericString, styles);

      numericString = "FFC86DA1";
      CallTryParse(numericString, NumberStyles.HexNumber);

      numericString = "0x8F8C";
      CallTryParse(numericString, NumberStyles.HexNumber);
   }

   private static void CallTryParse(string stringToConvert, NumberStyles
styles)
   {
      ulong number;
      bool result = UInt64.TryParse(stringToConvert, styles,
                                    CultureInfo.InvariantCulture, out
number);
      if (result)
         Console.WriteLine($"Converted '{stringToConvert}' to
{number}.");
      else
         Console.WriteLine($"Attempted conversion of '{stringToConvert}'
failed.");
   }
}
// The example displays the following output:
//       Converted '2106034' to 2106034.
//       Attempted conversion of '-10603' failed.
//       Converted '29103674.00' to 29103674.
//       Attempted conversion of '10345.72' failed.
//       Converted '41792210E-01' to 4179221.
//       Attempted conversion of '9112E-01' failed.
//       Converted '312E01' to 3120.
//       Converted 'FFC86DA1' to 4291325345.
//       Attempted conversion of '0x8F8C' failed.
```

Remarks

The TryParse(String, NumberStyles, IFormatProvider, UInt64) method is like the Parse(String, NumberStyles, IFormatProvider) method, except that it does not throw an exception if the conversion fails. This method eliminates the need to use exception handling to test for a FormatException if `s` is invalid and cannot be parsed successfully.

The `style` parameter defines the style elements (such as white space or a positive or negative sign) that are allowed in the `s` parameter for the parse operation to succeed. It must be a combination of bit flags from the NumberStyles enumeration. Depending on the value of `style`, the `s` parameter may include the following elements:

[*ws*][*$*][*sign*][*digits*,]*digits*[.*fractional_digits*][E[*sign*]*exponential_digits*][*ws*]

Items in square brackets ([and]) are optional. Or, if the `style` parameter includes NumberStyles.AllowHexSpecifier, the `s` parameter may include the following elements:

[*ws*]*hexdigits*[*ws*]

The following table describes each element.

Expand table

Element	Description
ws	Optional white space. White space can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingWhite flag, or at the end of `s` if `style` includes the NumberStyles.AllowTrailingWhite flag.
$	A culture-specific currency symbol. Its position in the string is defined by the CurrencyPositivePattern property of the NumberFormatInfo object returned by the GetFormat method of the `provider` parameter. The currency symbol can appear in `s` if `style` includes the NumberStyles.AllowCurrencySymbol flag.
sign	An optional sign. The sign can appear at the start of `s` if `style` includes the NumberStyles.AllowLeadingSign flag, and it can appear at the end of `s` if `style` includes the NumberStyles.AllowTrailingSign flag. Parentheses can be used in `s` to indicate a negative value if `style` includes the NumberStyles.AllowParentheses flag. However, if the negative sign is present, `s` can only represent the value zero for the parse operation to succeed.
digits	A sequence of digits from 0 through 9.

Element	Description
,	A culture-specific group separator. The group separator of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowThousands flag.
.	A culture-specific decimal point symbol. The decimal point symbol of the culture specified by `provider` can appear in `s` if `style` includes the NumberStyles.AllowDecimalPoint flag.
fractional_digits	One or more occurrences of the digit 0. Fractional digits can appear in `s` only if `style` includes the NumberStyles.AllowDecimalPoint flag.
E	The "e" or "E" character, which indicates that the value is represented in exponential (scientific) notation. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
exponential_digits	A sequence of digits from 0 through 9. The `s` parameter can represent a number in exponential notation if `style` includes the NumberStyles.AllowExponent flag.
hexdigits	A sequence of hexadecimal digits from 0 through f, or 0 through F.

> **Note**
>
> Any terminating NUL (U+0000) characters in `s` are ignored by the parsing operation, regardless of the value of the `style` argument.

A string with decimal digits only (which corresponds to the NumberStyles.None flag) always parses successfully. Most of the remaining NumberStyles members control elements that may be present, but are not required to be present, in this input string. The following table indicates how individual NumberStyles members affect the elements that may be present in `s`.

Expand table

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
None	Decimal digits only.
AllowDecimalPoint	The decimal point (.) and *fractional_digits* elements. However, *fractional_digits* must consist of only one or more 0 digits, or the method returns `false`.

Non-composite `NumberStyles` values	Elements permitted in value in addition to digits
AllowExponent	The "e" or "E" character, which indicates exponential notation, along with *exponential_digits*. If `s` represents a number in exponential notation, it cannot have a non-zero, fractional component.
AllowLeadingWhite	The *ws* element at the start of `s`.
AllowTrailingWhite	The *ws* element at the end of `s`.
AllowLeadingSign	The *sign* element before *digits*.
AllowTrailingSign	The *sign* element after *digits*.
AllowParentheses	The *sign* element in the form of parentheses enclosing a zero numeric value.
AllowThousands	The group separator (,) element.
AllowCurrencySymbol	The currency ($) element.
Currency	All elements. However, `s` cannot represent a hexadecimal number or a number in exponential notation.
Float	The *ws* element at the start or end of `s`, *sign* at the start of `s`, and the decimal point (.) symbol. The `s` parameter can also use exponential notation.
Number	The *ws*, *sign*, group separator (,), and decimal point (.) elements.
Any	All elements. However, `s` cannot represent a hexadecimal number.

If the NumberStyles.AllowHexSpecifier flag is used, `s` must be a hexadecimal value. Valid hexadecimal characters are 0-9, A-F, and a-f. A prefix such as "0x" is not supported and causes the parse operation to fail. The only other flags that can be present in `style` are NumberStyles.AllowLeadingWhite and NumberStyles.AllowTrailingWhite. (The NumberStyles enumeration has a composite style, HexNumber, that includes both white-space flags.)

> **Note**
>
> If `s` is the string representation of a hexadecimal number, it cannot be preceded by any decoration (such as `0x` or `&h`) that differentiates it as a hexadecimal number. This causes the conversion to fail.

The `provider` parameter is an IFormatProvider implementation. Its GetFormat method returns a NumberFormatInfo object that provides culture-specific information about the format of `s`. The `provider` parameter can be any one of the following:

- A CultureInfo object that represents the culture that supplies formatting information. Its GetFormat method returns the NumberFormatInfo object that provides numeric formatting information for that culture.
- A NumberFormatInfo object that provides numeric formatting information. (Its implementation of GetFormat just returns itself.)
- A custom object that implements IFormatProvider. Its GetFormat method instantiates and returns the NumberFormatInfo object that provides formatting information.

If `provider` is `null`, the NumberFormatInfo object for the current culture is used.

UInt64.IConvertible.ToBoolean(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToBoolean(IFormatProvider).

```
C#
bool IConvertible.ToBoolean (IFormatProvider provider);
```

Parameters

`provider` IFormatProvider

This parameter is ignored.

Returns

Boolean

`true` if the value of the current instance is not zero; otherwise, `false`.

Implements

ToBoolean(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToBoolean(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt64.IConvertible.ToByte(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToByte(IFormatProvider).

```
C#
byte IConvertible.ToByte (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Byte

The value of the current instance, converted to a Byte.

Implements

ToByte(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToByte(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt64.IConvertible.ToChar(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToChar(IFormatProvider).

C#

```
char IConvertible.ToChar (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Char

The value of the current instance, converted to a Char.

Implements

ToChar(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToChar(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1

UInt64.IConvertible.ToDateTime(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

This conversion is not supported. Attempting to use this method throws an InvalidCastException.

```
C#

DateTime IConvertible.ToDateTime (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

DateTime

This conversion is not supported. No value is returned.

Implements

ToDateTime(IFormatProvider)

Exceptions

InvalidCastException

In all cases.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.IConvertible.ToDecimal(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDecimal(IFormatProvider).

C#

```
decimal IConvertible.ToDecimal (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Decimal

The value of the current instance, converted to a Decimal.

Implements

ToDecimal(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDecimal(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.IConvertible.ToDouble(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToDouble(IFormatProvider).

```
C#
double IConvertible.ToDouble (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Double

The value of the current instance, converted to a Double.

Implements

ToDouble(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToDouble(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.IConvertible.ToInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt16(IFormatProvider).

C#

```
short IConvertible.ToInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int16

The value of the current instance, converted to an Int16.

Implements

ToInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt16(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.IConvertible.ToInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToInt32(IFormatProvider).

```
C#
int IConvertible.ToInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Int32

The value of the current instance, converted to an Int32.

Implements

ToInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToInt32(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UInt64.IConvertible.ToSingle(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToSingle(IFormatProvider).

```
C#
float IConvertible.ToSingle (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

Single

The value of the current instance, converted to a Single.

Implements

ToSingle(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the Convert.ToSingle(UInt64) method.

Applies to

Product	Versions

UInt64.IConvertible.ToType(Type, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

For a description of this member, see ToType(Type, IFormatProvider).

C#

```
object IConvertible.ToType (Type type, IFormatProvider provider);
```

Parameters

type Type

The type to which to convert this UInt64 value.

provider IFormatProvider

An IFormatProvider implementation that supplies information about the format of the returned value.

Returns

Object

The value of the current instance, converted to `type`.

Implements

ToType(Type, IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is to call the `static` (`Shared` in Visual Basic) Convert.ChangeType method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IConvertible.To UInt16(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt16(IFormatProvider).

C#

```
ushort IConvertible.ToUInt16 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt16

The value of the current instance, converted to a UInt16.

Implements

ToUInt16(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt16(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UInt64.IConvertible.ToUInt32(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt32(IFormatProvider).

C#

```
uint IConvertible.ToUInt32 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt32

The value of the current instance, converted to a UInt32.

Implements

ToUInt32(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface. The recommended alternative is

to call the Convert.ToUInt32(UInt64) method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt64.IConvertible.ToUInt64(IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

For a description of this member, see ToUInt64(IFormatProvider).

C#

```
ulong IConvertible.ToUInt64 (IFormatProvider provider);
```

Parameters

provider IFormatProvider

This parameter is ignored.

Returns

UInt64

The value of the current instance, unchanged.

Implements

ToUInt64(IFormatProvider)

Remarks

This member is an explicit interface member implementation. It can be used only when the UInt64 instance is cast to an IConvertible interface.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UInt64.IAdditionOperators<UInt64,UInt64,UInt64>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static ulong IAdditionOperators<ulong,ulong,ulong>.operator + (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to which `right` is added.

`right` UInt64

The value that's added to `left`.

Returns

UInt64

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IAdditionOperators<UInt64,UInt64,UInt64>.CheckedAddition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static ulong IAdditionOperators<ulong,ulong,ulong>.op_CheckedAddition (ulong
left, ulong right);
```

Parameters

`left` UInt64

The value to which `right` is added.

`right` UInt64

The value that's added to `left`.

Returns

UInt64

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.IBinaryInteger<UInt64>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<ulong>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IBinaryInteger<UInt64>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<ulong>.TryWriteLittleEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

UInt64.IBitwiseOperators<UInt64,UInt64,UInt64>.BitwiseAnd Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

```
C#

static ulong IBitwiseOperators<ulong,ulong,ulong>.operator & (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to `and` with `right`.

`right` UInt64

The value to `and` with `left`.

Returns

UInt64

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IBitwiseOperators<UInt64,UInt64,UInt64>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

```
C#

static ulong IBitwiseOperators<ulong,ulong,ulong>.operator | (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to `or` with `right`.

`right` UInt64

The value to `or` with `left`.

Returns

UInt64

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IBitwiseOperators<UInt64,UInt64,UInt64>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static ulong IBitwiseOperators<ulong,ulong,ulong>.operator ^ (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to xor with `right`.

`right` UInt64

The value to xor with `left`.

Returns

UInt64

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IBitwiseOperators<UInt64,UInt64,UInt64>.OnesComplementOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

```
C#
static ulong IBitwiseOperators<ulong,ulong,ulong>.operator ~ (ulong value);
```

Parameters

`value` UInt64

The value for which to compute the ones-complement.

Returns

UInt64

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IComparisonOperators<UInt64,UInt64,Boolean>.GreaterThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<ulong,ulong,bool>.operator > (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to compare with `right`.

`right` UInt64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IComparisonOperators<UInt64,UInt64,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<ulong,ulong,bool>.operator >= (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to compare with `right`.

`right` UInt64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IComparisonOperators<UInt64,UInt64,Boolean>.LessThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<ulong,ulong,bool>.operator < (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to compare with `right`.

`right` UInt64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IDivisionOperators<UInt64,UInt64,UInt64>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static ulong IDivisionOperators<ulong,ulong,ulong>.operator / (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value that `right` divides.

`right` UInt64

The value that divides `left`.

Returns

UInt64

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IEqualityOperators<UInt64,UInt64,Boolean>.Equality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine equality.

```
C#

static bool IEqualityOperators<ulong,ulong,bool>.operator == (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to compare with `right`.

`right` UInt64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is equal to `right`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IEqualityOperators<UInt64,UInt64,Boolean>.Inequality Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine inequality.

```
C#

static bool IEqualityOperators<ulong,ulong,bool>.operator != (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value to compare with `right`.

`right` UInt64

The value to compare with `left`.

Returns

Boolean

`true` if `left` is not equal to `right`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IIncrementOperators<UInt64>.Increment(UInt64) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#
static ulong IIncrementOperators<ulong>.operator ++ (ulong value);
```

Parameters

`value` UInt64

The value to increment.

Returns

UInt64

The result of incrementing `value`.

Implements

Increment(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.IMinMaxValue<UInt64>.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the maximum value of the current type.

C#

```
static ulong System.Numerics.IMinMaxValue<System.UInt64>.MaxValue { get; }
```

Property Value

UInt64

Implements

MaxValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IMinMaxValue<UInt64>.MinValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the minimum value of the current type.

C#

```
static ulong System.Numerics.IMinMaxValue<System.UInt64>.MinValue { get; }
```

Property Value

UInt64

Implements

MinValue

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IModulusOperators<UInt64,UInt64,UInt64>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static ulong IModulusOperators<ulong,ulong,ulong>.operator % (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value that `right` divides.

`right` UInt64

The value that divides `left`.

Returns

UInt64

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IMultiplicativeIdentity<UInt64,UInt64>.MultiplicativeIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the multiplicative identity of the current type.

C#

```
static ulong
System.Numerics.IMultiplicativeIdentity<System.UInt64,System.UInt64>.MultiplicativeIdentity { get; }
```

Property Value

UInt64

Implements

MultiplicativeIdentity

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IMultiplyOperators<UInt64,UInt64,UInt64>.CheckedMultiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static ulong IMultiplyOperators<ulong,ulong,ulong>.op_CheckedMultiply (ulong
left, ulong right);
```

Parameters

`left` UInt64

The value that `right` multiplies.

`right` UInt64

The value that multiplies `left`.

Returns

UInt64

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IMultiplyOperators<UInt64,UInt64,UInt64>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static ulong IMultiplyOperators<ulong,ulong,ulong>.operator * (ulong left,
ulong right);
```

Parameters

`left` UInt64

The value that `right` multiplies.

`right` UInt64

The value that multiplies `left`.

Returns

UInt64

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumber<UInt64>.CopySign(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
static ulong INumber<ulong>.CopySign (ulong value, ulong sign);
```

Parameters

`value` UInt64

The value whose magnitude is used in the result.

`sign` UInt64

The value whose sign is used in the result.

Returns

UInt64

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumber<UInt64>.MaxNumber(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater and returning the other value if an input is `NaN`.

C#

```
static ulong INumber<ulong>.MaxNumber (ulong x, ulong y);
```

Parameters

x UInt64

The value to compare with `y`.

y UInt64

The value to compare with `x`.

Returns

UInt64

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumber<UInt64>.MinNumber(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static ulong INumber<ulong>.MinNumber (ulong x, ulong y);
```

Parameters

x UInt64

The value to compare with `y`.

y UInt64

The value to compare with `x`.

Returns

UInt64

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.Abs(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static ulong INumberBase<ulong>.Abs (ulong value);
```

Parameters

`value` UInt64

The value for which to get its absolute.

Returns

UInt64

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsCanonical(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

```
C#
static bool INumberBase<ulong>.IsCanonical (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsComplexNumber(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

C#

```
static bool INumberBase<ulong>.IsComplexNumber (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.IsFinite(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<ulong>.IsFinite (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsImaginaryNumber(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<ulong>.IsImaginaryNumber (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.IsInfinity(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<ulong>.IsInfinity (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsInteger(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<ulong>.IsInteger (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsNaN(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<ulong>.IsNaN (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsNegative(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<ulong>.IsNegative (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsNegativeInfinity(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative infinity.

C#

```
static bool INumberBase<ulong>.IsNegativeInfinity (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is negative infinity; otherwise, `false`.

Implements

IsNegativeInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.IsNormal(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<ulong>.IsNormal (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.INumberBase<UInt64>.IsPositive(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

```
C#
static bool INumberBase<ulong>.IsPositive (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.IsRealNumber(UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

```
C#
static bool INumberBase<ulong>.IsRealNumber (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is zero.

```
C#
static bool INumberBase<ulong>.IsZero (ulong value);
```

Parameters

`value` UInt64

The value to be checked.

Returns

Boolean

`true` if `value` is zero; otherwise, `false`.

Implements

IsZero(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.MaxMagnitude(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static ulong INumberBase<ulong>.MaxMagnitude (ulong x, ulong y);
```

Parameters

x UInt64

The value to compare with `y`.

y UInt64

The value to compare with `x`.

Returns

UInt64

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.MinMagnitude(UInt64, UInt64) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

C#

```
static ulong INumberBase<ulong>.MinMagnitude (ulong x, ulong y);
```

Parameters

x UInt64

The value to compare with `y`.

y UInt64

The value to compare with `x`.

Returns

UInt64

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.INumberBase<UInt64>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<ulong>.TryConvertToChecked<TOther> (ulong value, out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt64

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.INumberBase<UInt64>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<ulong>.TryConvertToSaturating<TOther> (ulong value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt64

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.INumberBase<UInt64>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

C#

```
static bool INumberBase<ulong>.TryConvertToTruncating<TOther> (ulong value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UInt64

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.INumberBase<UInt64>.Zero Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value `0` for the type.

C#

```
static ulong System.Numerics.INumberBase<System.UInt64>.Zero { get; }
```

Property Value

UInt64

Implements

Zero

Applies to

Product	Versions
.NET	7, 8, 9

UInt64.IShift Operators<UInt64,Int32,UInt64>.Left Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

```
C#

static ulong IShiftOperators<ulong,int,ulong>.operator << (ulong value, int
shiftAmount);
```

Parameters

`value` UInt64

The value that is shifted left by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted left.

Returns

UInt64

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IShift Operators<UInt64,Int32,UInt64>.Right Shift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static ulong IShiftOperators<ulong,int,ulong>.operator >> (ulong value, int
shiftAmount);
```

Parameters

`value` UInt64

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt64

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IShift Operators<UInt64,Int32,UInt64>.UnsignedRightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static ulong IShiftOperators<ulong,int,ulong>.op_UnsignedRightShift (ulong
value, int shiftAmount);
```

Parameters

`value` UInt64

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UInt64

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.ISubtraction Operators<UInt64,UInt64,UInt64>.CheckedSubtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static ulong ISubtractionOperators<ulong,ulong,ulong>.op_CheckedSubtraction
(ulong left, ulong right);
```

Parameters

`left` UInt64

The value from which `right` is subtracted.

`right` UInt64

The value that's subtracted from `left`.

Returns

UInt64

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.ISubtractionOperators<UInt64,UInt64,UInt64>.Subtraction Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static ulong ISubtractionOperators<ulong,ulong,ulong>.operator - (ulong
left, ulong right);
```

Parameters

`left` UInt64

The value from which `right` is subtracted.

`right` UInt64

The value that's subtracted from `left`.

Returns

UInt64

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IUnaryNegationOperators<UInt64,UInt64>.CheckedUnaryNegation Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static ulong IUnaryNegationOperators<ulong,ulong>.op_CheckedUnaryNegation
(ulong value);
```

Parameters

`value` UInt64

The value for which to compute the unary negation.

Returns

UInt64

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UInt64.IUnaryNegationOperators<UInt64,UInt64>.UnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#
static ulong IUnaryNegationOperators<ulong,ulong>.operator - (ulong value);
```

Parameters

`value` UInt64

The value for which to compute the unary negation.

Returns

UInt64

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UInt64.IUnaryPlusOperators<UInt64,UInt64>.UnaryPlus(UInt64) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#
static ulong IUnaryPlusOperators<ulong,ulong>.operator + (ulong value);
```

Parameters

`value` UInt64

The value for which to compute the unary plus.

Returns

UInt64

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

IUnsignedNumber<UIntPtr> , IUtf8SpanFormattable ,

IUtf8SpanParsable<UIntPtr> , IUtf8SpanParsable<TSelf>

Remarks

The UIntPtr type is designed to be an integer whose size is the same as a pointer. That is, an instance of this type is expected to be 32-bits in a 32-bit process and 64-bits in a 64-bit process.

The UIntPtr type can be used by languages that support pointers, and as a common means of referring to data between languages that do and do not support pointers. UIntPtr objects can also be used to hold handles.

> **Note**
>
> Using **UIntPtr** as a pointer or a handle is error prone and unsafe. It is simply an integer type that can be used as an interchange format for pointers and handles due to being the same size. Outside of specific interchange requirements, such as for passing data to a language that doesn't support pointers, a correctly typed pointer should be used to represent pointers and **SafeHandle** should be used to represent handles.

This type implements the ISerializable. In .NET 5 and later versions, this type also implements the IFormattable interfaces. In .NET 7 and later versions, this type also implements the IBinaryInteger<TSelf>, IMinMaxValue<TSelf>, and IUnsignedNumber<TSelf> interfaces.

In C# starting from version 9.0, you can use the built-in `nuint` type to define native-sized integers. This type is represented by the UIntPtr type internally and provides operations and conversions that are appropriate for integer types. For more information, see nint and nuint types.

In C# starting from version 11 and when targeting the .NET 7 or later runtime, `nuint` is an alias for UIntPtr in the same way that `uint` is an alias for UInt32.

Constructors

Expand table

UInt Ptr(UInt32)	Initializes a new instance of the UIntPtr structure using the specified 32-bit unsigned integer.
UInt Ptr(UInt64)	Initializes a new instance of UIntPtr using the specified 64-bit unsigned integer.
UIntPtr(Void*)	Initializes a new instance of UIntPtr using the specified pointer to an unspecified type.

Fields

Expand table

Zero	A read-only field that represents an unsigned integer that has been initialized to zero.

Properties

Expand table

MaxValue	Represents the largest possible value of UIntPtr.
MinValue	Represents the smallest possible value of UIntPtr.
Size	Gets the size of this instance.

Methods

Expand table

Add(UIntPtr, Int32)	Adds an offset to an unsigned integer.
Clamp(UIntPtr, UIntPtr, UIntPtr)	Clamps a value to an inclusive minimum and maximum value.
CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(UIntPtr)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

CreateChecked<TOther>(TOther)	Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.
CreateSaturating<TOther>(TOther)	Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.
CreateTruncating<TOther>(TOther)	Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.
DivRem(UIntPtr, UIntPtr)	Computes the quotient and remainder of two values.
Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UIntPtr)	Indicates whether the current object is equal to another object of the same type.
GetHashCode()	Returns the hash code for this instance.
IsEvenInteger(UIntPtr)	Determines if a value represents an even integral number.
IsOddInteger(UIntPtr)	Determines if a value represents an odd integral number.
IsPow2(UIntPtr)	Determines if a value is a power of two.
LeadingZeroCount(UIntPtr)	Computes the number of leading zeros in a value.
Log2(UIntPtr)	Computes the log2 of a value.
Max(UIntPtr, UIntPtr)	Compares two values to compute which is greater.
Min(UIntPtr, UIntPtr)	Compares two values to compute which is lesser.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the read-only span of characters representation of a number in optionally specified style and optionally specified culture-specific format to its unsigned native integer equivalent.
Parse(String)	Converts the string representation of a number to its unsigned native integer equivalent.

Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its unsigned native integer equivalent.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its unsigned native integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent.
PopCount(UIntPtr)	Computes the number of bits that are set in a value.
RotateLeft(UIntPtr, Int32)	Rotates a value left by a given amount.
RotateRight(UIntPtr, Int32)	Rotates a value right by a given amount.
Sign(UIntPtr)	Computes the sign of a value.
Subtract(UIntPtr, Int32)	Subtracts an offset from an unsigned integer.
ToPointer()	Converts the value of this instance to a pointer to an unspecified type.
ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
ToUInt32()	Converts the value of this instance to a 32-bit unsigned integer.
ToUInt64()	Converts the value of this instance to a 64-bit unsigned integer.
TrailingZeroCount(UIntPtr)	Computes the number of trailing zeros in a value.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.
TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormat Provider)	Tries to format the value of the current instance into the provided span of characters.

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UIntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UIntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Byte>, UIntPtr)	Tries to convert a UTF-8 character span containing the string representation of a number to its unsigned integer equivalent.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UIntPtr)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UIntPtr)	Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, UIntPtr)	Converts the read-only span of characters representation of a number to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, IFormatProvider, UIntPtr)	Tries to parse a string into a value.
TryParse(String, NumberStyles, IFormatProvider, UIntPtr)	Converts the string representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, UIntPtr)	Converts the string representation of a number to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.

Operators

Expand table

Addition(UIntPtr, Int32)	Adds an offset to an unsigned integer.
Equality(UIntPtr, UIntPtr)	Determines whether two specified instances of UIntPtr are equal.
Explicit(UInt32 to UIntPtr)	Converts the value of a 32-bit unsigned integer to an UIntPtr.
Explicit(UInt64 to UIntPtr)	Converts the value of a 64-bit unsigned integer to an UIntPtr.

Explicit(UIntPtr to UInt32)	Converts the value of the specified UIntPtr to a 32-bit unsigned integer.
Explicit(UIntPtr to UInt64)	Converts the value of the specified UIntPtr to a 64-bit unsigned integer.
Explicit(UIntPtr to Void*)	Converts the value of the specified UIntPtr to a pointer to an unspecified type. This API is not CLS-compliant.
Explicit(Void* to UIntPtr)	Converts the specified pointer to an unspecified type to an UIntPtr. This API is not CLS-compliant.
Inequality(UIntPtr, UIntPtr)	Determines whether two specified instances of UIntPtr are not equal.
Subtraction(UIntPtr, Int32)	Subtracts an offset from an unsigned integer.

Explicit Interface Implementations

Expand table

IAdditionOperators<UIntPtr,UIntPtr,UIntPtr>.Addition(UIntPtr, UIntPtr)	Adds two values together to compute their sum.
IAdditionOperators<UIntPtr,UIntPtr,UIntPtr>.CheckedAddition(UIntPtr, UIntPtr)	Adds two values together to compute their sum.
IAdditiveIdentity<UIntPtr,UIntPtr>.AdditiveIdentity	Gets the additive identity of the current type.
IBinaryInteger<UIntPtr>.GetByteCount()	Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).
IBinaryInteger<UIntPtr>.GetShortestBitLength()	Gets the length, in bits, of the shortest two's complement representation of the current value.
IBinaryInteger<UIntPtr>.TryReadBigEndian(ReadOnlySpan<Byte>, Boolean, UIntPtr)	
IBinaryInteger<UIntPtr>.TryReadLittleEndian(ReadOnlySpan<Byte>, Boolean, UIntPtr)	
IBinaryInteger<UIntPtr>.TryWriteBigEndian(Span<Byte>, Int32)	Tries to write the current value, in big-endian format, to a given span.
IBinaryInteger<UIntPtr>.TryWriteLittleEndian(Span<Byte>, Int32)	Tries to write the current value, in little-endian format, to a given span.

IBinaryNumber<UIntPtr>.AllBitsSet	Gets an instance of the binary type in which all bits are set.
IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.BitwiseAnd(UIntPtr, UIntPtr)	Computes the bitwise-and of two values.
IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.BitwiseOr(UIntPtr, UIntPtr)	Computes the bitwise-or of two values.
IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.ExclusiveOr(UIntPtr, UIntPtr)	Computes the exclusive-or of two values.
IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.OnesComplement(UIntPtr)	Computes the ones-complement representation of a given value.
IComparisonOperators<UIntPtr,UIntPtr,Boolean>.GreaterThan(UIntPtr, UIntPtr)	Compares two values to determine which is greater.
IComparisonOperators<UIntPtr,UIntPtr,Boolean>.GreaterThanOrEqual(UIntPtr, UIntPtr)	Compares two values to determine which is greater or equal.
IComparisonOperators<UIntPtr,UIntPtr,Boolean>.LessThan(UIntPtr, UIntPtr)	Compares two values to determine which is less.
IComparisonOperators<UIntPtr,UIntPtr,Boolean>.LessThanOrEqual(UIntPtr, UIntPtr)	Compares two values to determine which is less or equal.
IDecrementOperators<UIntPtr>.CheckedDecrement(UIntPtr)	Decrements a value.
IDecrementOperators<UIntPtr>.Decrement(UIntPtr)	Decrements a value.
IDivisionOperators<UIntPtr,UIntPtr,UIntPtr>.Division(UIntPtr, UIntPtr)	Divides one value by another to compute their quotient.
IIncrementOperators<UIntPtr>.CheckedIncrement(UIntPtr)	Increments a value.
IIncrementOperators<UIntPtr>.Increment(UIntPtr)	Increments a value.
IMinMaxValue<UIntPtr>.MaxValue	Gets the maximum value of the current type.
IMinMaxValue<UIntPtr>.MinValue	Gets the minimum value of the current type.
IModulusOperators<UIntPtr,UIntPtr,UIntPtr>.Modulus(UIntPtr, UIntPtr)	Divides two values together to compute their modulus or remainder.

IMultiplicativeIdentity<UIntPtr,UIntPtr>.MultiplicativeIdentity	Gets the multiplicative identity of the current type.
IMultiplyOperators<UIntPtr,UIntPtr,UIntPtr>.CheckedMultiply(UIntPtr, UIntPtr)	Multiplies two values together to compute their product.
IMultiplyOperators<UIntPtr,UIntPtr,UIntPtr>.Multiply(UIntPtr, UIntPtr)	Multiplies two values together to compute their product.
INumber<UIntPtr>.CopySign(UIntPtr, UIntPtr)	Copies the sign of a value to the sign of another value.
INumber<UIntPtr>.MaxNumber(UIntPtr, UIntPtr)	Compares two values to compute which is greater and returning the other value if an input is `NaN`.
INumber<UIntPtr>.MinNumber(UIntPtr, UIntPtr)	Compares two values to compute which is lesser and returning the other value if an input is `NaN`.
INumberBase<UIntPtr>.Abs(UIntPtr)	Computes the absolute of a value.
INumberBase<UIntPtr>.IsCanonical(UIntPtr)	Determines if a value is in its canonical representation.
INumberBase<UIntPtr>.IsComplexNumber(UIntPtr)	Determines if a value represents a complex number.
INumberBase<UIntPtr>.IsFinite(UIntPtr)	Determines if a value is finite.
INumberBase<UIntPtr>.IsImaginaryNumber(UIntPtr)	Determines if a value represents a pure imaginary number.
INumberBase<UIntPtr>.IsInfinity(UIntPtr)	Determines if a value is infinite.
INumberBase<UIntPtr>.IsInteger(UIntPtr)	Determines if a value represents an integral number.
INumberBase<UIntPtr>.IsNaN(UIntPtr)	Determines if a value is NaN.
INumberBase<UIntPtr>.IsNegative(UIntPtr)	Determines if a value is negative.
INumberBase<UIntPtr>.IsNegativeInfinity(UIntPtr)	Determines if a value is negative infinity.
INumberBase<UIntPtr>.IsNormal(UIntPtr)	Determines if a value is normal.
INumberBase<UIntPtr>.IsPositive(UIntPtr)	Determines if a value is positive.
INumberBase<UIntPtr>.IsPositiveInfinity(UIntPtr)	Determines if a value is positive infinity.
INumberBase<UIntPtr>.IsRealNumber(UIntPtr)	Determines if a value represents a real number.

INumberBase<UIntPtr>.IsSubnormal(UIntPtr)	Determines if a value is subnormal.
INumberBase<UIntPtr>.IsZero(UIntPtr)	Determines if a value is zero.
INumberBase<UIntPtr>.MaxMagnitude(UIntPtr, UIntPtr)	Compares two values to compute which is greater.
INumberBase<UIntPtr>.MaxMagnitudeNumber(UIntPtr, UIntPtr)	Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.
INumberBase<UIntPtr>.MinMagnitude(UIntPtr, UIntPtr)	Compares two values to compute which is lesser.
INumberBase<UIntPtr>.MinMagnitudeNumber(UIntPtr, UIntPtr)	Compares two values to compute which has the lesser magnitude and returning the other value if an input is `NaN`.
INumberBase<UIntPtr>.One	Gets the value `1` for the type.
INumberBase<UIntPtr>.Radix	Gets the radix, or base, for the type.
INumberBase<UIntPtr>.TryConvertFromChecked<TOther>(TOther, UIntPtr)	
INumberBase<UIntPtr>.TryConvertFromSaturating<TOther>(TOther, UIntPtr)	
INumberBase<UIntPtr>.TryConvertFromTruncating<TOther>(TOther, UIntPtr)	
INumberBase<UIntPtr>.TryConvertToChecked<TOther>(UIntPtr, TOther)	Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.
INumberBase<UIntPtr>.TryConvertToSaturating<TOther>(UIntPtr, TOther)	Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.
INumberBase<UIntPtr>.TryConvertToTruncating<TOther>(UIntPtr, TOther)	Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.
INumberBase<UIntPtr>.Zero	Gets the value `0` for the type.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo object with the data needed to serialize the current UIntPtr object.
IShiftOperators<UIntPtr,Int32,UIntPtr>.LeftShift(UIntPtr, Int32)	Shifts a value left by a given amount.
IShiftOperators<UIntPtr,Int32,UIntPtr>.RightShift(UIntPtr, Int32)	Shifts a value right by a given amount.

IShiftOperators<UIntPtr,Int32,UIntPtr>.UnsignedRightShift(UIntPtr, Int32)	Shifts a value right by a given amount.
ISubtractionOperators<UIntPtr,UIntPtr,UIntPtr>.CheckedSubtraction(UIntPtr, UIntPtr)	Subtracts two values to compute their difference.
ISubtractionOperators<UIntPtr,UIntPtr,UIntPtr>.Subtraction(UIntPtr, UIntPtr)	Subtracts two values to compute their difference.
IUnaryNegationOperators<UIntPtr,UIntPtr>.CheckedUnaryNegation(UIntPtr)	Computes the checked unary negation of a value.
IUnaryNegationOperators<UIntPtr,UIntPtr>.UnaryNegation(UIntPtr)	Computes the unary negation of a value.
IUnaryPlusOperators<UIntPtr,UIntPtr>.UnaryPlus(UIntPtr)	Computes the unary plus of a value.

UIntPtr Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of UIntPtr.

Overloads

Expand table

UIntPtr(UInt32)	Initializes a new instance of the UIntPtr structure using the specified 32-bit unsigned integer.
UIntPtr(UInt64)	Initializes a new instance of UIntPtr using the specified 64-bit unsigned integer.
UIntPtr(Void*)	Initializes a new instance of UIntPtr using the specified pointer to an unspecified type.

UIntPtr(UInt32)

Initializes a new instance of the UIntPtr structure using the specified 32-bit unsigned integer.

C#

```
public UIntPtr (uint value);
```

Parameters

`value` UInt32

A 32-bit unsigned integer.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr(UInt64)

Initializes a new instance of UIntPtr using the specified 64-bit unsigned integer.

C#

```
public UIntPtr (ulong value);
```

Parameters

`value` UInt64

A 64-bit unsigned integer.

Exceptions

OverflowException

In a 32-bit process, `value` is too large to represent as an UIntPtr.

Remarks

An exception is only thrown if the value of `value` requires more bits than the executing process supports.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7,

Product	Versions

.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr(Void*)

> Important
>
> This API is not CLS-compliant.

Initializes a new instance of UIntPtr using the specified pointer to an unspecified type.

```
C#
public UIntPtr (void* value);
```

Parameters

`value` Void*

A pointer to an unspecified type.

UIntPtr.Zero Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

A read-only field that represents an unsigned integer that has been initialized to zero.

```
C#
public static readonly UIntPtr Zero;
```

Field Value

UIntPtr

Remarks

The value of this field is not equivalent to `null`. Use this field to efficiently determine whether an instance of UIntPtr has been set to a value other than zero.

For example, assume the variable, uip, is an instance of UIntPtr. You can determine if it has been set by comparing it to the value returned by a constructor, for example, `if uip != new UIntPtr(0)...`. However, invoking a constructor to get an uninitialized pointer is inefficient. It is better to code either `if uip != UIntPtr.Zero...` or `if !UIntPtr.Zero.Equals(uip)...`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UIntPtr.MaxValue Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the largest possible value of UIntPtr.

C#

```
public static UIntPtr MaxValue { get; }
```

Property Value

UIntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxValue

Applies to

Product	Versions
.NET	5, 6, 7, 8, 9

UIntPtr.Size Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the size of this instance.

C#

```
public static int Size { get; }
```

Property Value

Int32

The size of an unsigned integer in the executing process, measured in bytes. The value of this property is 4 in a 32-bit process, and 8 in a 64-bit process. You can define the process type by setting the `/platform` switch when you compile your code with the C# and Visual Basic compilers.

Applies to

Product	Versions

UIntPtr.Add(UIntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds an offset to an unsigned integer.

C#

```
public static UIntPtr Add (UIntPtr pointer, int offset);
```

Parameters

pointer UIntPtr

The unsigned integer to add the offset to.

offset Int32

The offset to add.

Returns

UIntPtr

A new unsigned integer that reflects the addition of `offset` to `pointer`.

Examples

The following example instantiates a UIntPtr object that points to the beginning of a ten-element array, and then calls the Add method to iterate the elements in the array.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      int[] arr = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
```

```
        UIntPtr ptr = (UIntPtr) arr[0];
        for (int ctr = 0; ctr < arr.Length; ctr++)
        {
           UIntPtr newPtr = UIntPtr.Add(ptr, ctr);
           Console.Write("{0}   ", newPtr);
        }
    }
}
// The example displays the following output:
//       1   2   3   4   5   6   7   8   9   10
```

Remarks

The Add method does not throw an exception if the result is too large to represent as an unsigned integer in the executing process. Instead, the addition operation is performed in an unchecked context.

Languages that do not support operator overloading or custom operators can use this method to add an offset to the value of a pointer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr.Clamp(UIntPtr, UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Clamps a value to an inclusive minimum and maximum value.

C#

```
public static UIntPtr Clamp (UIntPtr value, UIntPtr min, UIntPtr max);
```

Parameters

`value` UIntPtr

The value to clamp.

`min` UIntPtr

The inclusive minimum to which `value` should clamp.

`max` UIntPtr

The inclusive maximum to which `value` should clamp.

Returns

UIntPtr

The result of clamping `value` to the inclusive range of `min` and `max`.

Implements

Clamp(TSelf, TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

CompareTo(Object)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.
CompareTo(UIntPtr)	Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

CompareTo(Object)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (object? value);
```

Parameters

`value` Object

An object to compare, or `null`.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(Object)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

CompareTo(UIntPtr)

Compares the current instance with another object of the same type and returns an integer that indicates whether the current instance precedes, follows, or occurs in the same position in the sort order as the other object.

C#

```
public int CompareTo (UIntPtr value);
```

Parameters

`value` UIntPtr

An unsigned native integer to compare.

Returns

Int32

A value that indicates the relative order of the objects being compared. The return value has these meanings:

Expand table

Value	Meaning
Less than zero	This instance precedes `value` in the sort order.
Zero	This instance occurs in the same position in the sort order as `value`.
Greater than zero	This instance follows `value` in the sort order.

Implements

CompareTo(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

UIntPtr.CreateChecked<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

public static UIntPtr CreateChecked<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value that's used to create the instance of `TSelf`.

Returns

UIntPtr

An instance of `TSelf` created from `value`.

Implements

CreateChecked<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.CreateSaturating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, saturating any values that fall outside the representable range of the current type.

```
C#

public static UIntPtr CreateSaturating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

UIntPtr

An instance of `TSelf` created from `value`, saturating if `value` falls outside the representable range of `TSelf`.

Implements

CreateSaturating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.CreateTruncating<TOther>(TOther) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates an instance of the current type from a value, truncating any values that fall outside the representable range of the current type.

```
C#

public static UIntPtr CreateTruncating<TOther> (TOther value) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type of `value`.

Parameters

`value` TOther

The value which is used to create the instance of `TSelf`.

Returns

UIntPtr

An instance of `TSelf` created from `value`, truncating if `value` falls outside the representable range of `TSelf`.

Implements

CreateTruncating<TOther>(TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.DivRem(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the quotient and remainder of two values.

```
C#

public static (UIntPtr Quotient, UIntPtr Remainder) DivRem (UIntPtr left,
UIntPtr right);
```

Parameters

`left` UIntPtr

The value which `right` divides.

`right` UIntPtr

The value which divides `left`.

Returns

ValueTuple<UIntPtr,UIntPtr>

The quotient and remainder of `left` divided-by `right`.

Implements

DivRem(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Equals(Object)	Returns a value indicating whether this instance is equal to a specified object.
Equals(UIntPtr)	Indicates whether the current object is equal to another object of the same type.

Equals(Object)

Returns a value indicating whether this instance is equal to a specified object.

```
C#

public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with this instance or `null`.

Returns

Boolean

`true` if `obj` is an instance of UIntPtr and equals the value of this instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Equals(UIntPtr)

Indicates whether the current object is equal to another object of the same type.

C#

```
public bool Equals (UIntPtr other);
```

Parameters

`other` UIntPtr

An object to compare with this object.

Returns

Boolean

`true` if the current object is equal to the `other` parameter; otherwise, `false`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

UIntPtr.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UIntPtr.IsEvenInteger(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an even integral number.

```
C#
public static bool IsEvenInteger (UIntPtr value);
```

Parameters

value UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is an even integer; otherwise, `false`.

Implements

IsEvenInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `2.0` will return `true` while `2.2` will return `false`.

A return value of `false` does not imply that IsOddInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IsOddInteger(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an odd integral number.

```
C#
public static bool IsOddInteger (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is an odd integer; otherwise, `false`.

Implements

IsOddInteger(TSelf)

Remarks

This method correctly handles floating-point values and so `3.0` will return `true` while `3.3` will return `false`.

A return value of `false` does not imply that IsEvenInteger(TSelf) will return `true`. A number with a fractional portion, for example, `3.3`, is not even or odd.

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IsPow2(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is a power of two.

C#

```
public static bool IsPow2 (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a power of two; otherwise, `false`.

Implements

IsPow2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

.NET feedback

UIntPtr.LeadingZeroCount(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of leading zeros in a value.

```
C#
public static UIntPtr LeadingZeroCount (UIntPtr value);
```

Parameters

`value` UIntPtr

The value whose leading zeroes are to be counted.

Returns

UIntPtr

The number of leading zeros in `value`.

Implements

LeadingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.Log2(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the log2 of a value.

```
C#
public static UIntPtr Log2 (UIntPtr value);
```

Parameters

`value` UIntPtr

The value whose log2 is to be computed.

Returns

UIntPtr

The log2 of `value`.

Implements

Log2(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.Max(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

```
C#
public static UIntPtr Max (UIntPtr x, UIntPtr y);
```

Parameters

x UIntPtr

The value to compare with `y`.

y UIntPtr

The value to compare with `x`.

Returns

UIntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

Max(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `maximum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.Min(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

```
C#
public static UIntPtr Min (UIntPtr x, UIntPtr y);
```

Parameters

x UIntPtr

The value to compare with `y`.

y UIntPtr

The value to compare with `x`.

Returns

UIntPtr

`x` if it is less than `y`; otherwise, `y`.

Implements

Min(TSelf, TSelf)

Remarks

For IFloatingPoint<TSelf> this method matches the IEEE 754:2019 `minimum` function. This requires NaN inputs to be propagated back to the caller and for `-0.0` to be treated as less than `+0.0`.

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(String)	Converts the string representation of a number to its unsigned native integer equivalent.
Parse(ReadOnlySpan<Byte>, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, IFormatProvider)	Parses a span of characters into a value.
Parse(String, NumberStyles)	Converts the string representation of a number in a specified style to its unsigned native integer equivalent.
Parse(String, IFormatProvider)	Converts the string representation of a number in a specified culture-specific format to its unsigned native integer equivalent.
Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)	Parses a span of UTF-8 characters into a value.
Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)	Converts the read-only span of characters representation of a number in optionally specified style and optionally specified culture-specific format to its unsigned native integer equivalent.
Parse(String, NumberStyles, IFormatProvider)	Converts the string representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent.

Parse(String)

Converts the string representation of a number to its unsigned native integer equivalent.

```
C#
public static UIntPtr Parse (string s);
```

Parameters

s String

A string containing a number to convert.

Returns

UIntPtr

An unsigned native integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```
C#

public static UIntPtr Parse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UIntPtr

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, IFormatProvider)

Parses a span of characters into a value.

```
C#

public static UIntPtr Parse (ReadOnlySpan<char> s, IFormatProvider?
provider);
```

Parameters

`s` ReadOnlySpan<Char>

The span of characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

Returns

UIntPtr

The result of parsing `s`.

Implements

Parse(ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

Parse(String, NumberStyles)

Converts the string representation of a number in a specified style to its unsigned native integer equivalent.

C#

```
public static UIntPtr Parse (string s, System.Globalization.NumberStyles
style);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`.

Returns

UIntPtr

An unsigned native integer equivalent to the number contained in `s`.

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value or `style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(String, IFormatProvider)

Converts the string representation of a number in a specified culture-specific format to its unsigned native integer equivalent.

C#

```
public static UIntPtr Parse (string s, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UIntPtr

An unsigned native integer equivalent to the number contained in `s`.

Implements

Parse(String, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Parses a span of UTF-8 characters into a value.

```C#
public static UIntPtr Parse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

Returns

UIntPtr

The result of parsing `utf8Text`.

Implements

Parse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Converts the read-only span of characters representation of a number in optionally specified style and optionally specified culture-specific format to its unsigned native

integer equivalent.

```C#
public static UIntPtr Parse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style =
System.Globalization.NumberStyles.Integer, IFormatProvider? provider =
default);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert.

`style` NumberStyles

An optional bitwise combination of the enumeration values that indicates the style elements that can be present in `s`. The default value is Integer.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information about `s`. The default value is `default`.

Returns

UIntPtr

An unsigned native integer equivalent to the number contained in `s`.

Implements

Parse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider)

Exceptions

ArgumentException

`style` is not a NumberStyles value or `style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Parse(String, NumberStyles, IFormatProvider)

Converts the string representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent.

```
C#

public static UIntPtr Parse (string s, System.Globalization.NumberStyles
style, IFormatProvider? provider);
```

Parameters

`s` String

A string containing a number to convert.

`style` NumberStyles

A bitwise combination of the enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

Returns

UIntPtr

An unsigned native integer equivalent to the number contained in `s`.

Implements

Parse(String, NumberStyles, IFormatProvider)

Exceptions

ArgumentNullException

`s` is `null`.

ArgumentException

`style` is not a NumberStyles value or `style` is not a combination of AllowHexSpecifier and HexNumber values.

FormatException

`s` is not in the correct format.

OverflowException

`s` represents a number less than MinValue or greater than MaxValue.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

UIntPtr.PopCount(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of bits that are set in a value.

C#

```
public static UIntPtr PopCount (UIntPtr value);
```

Parameters

`value` UIntPtr

The value whose set bits are to be counted.

Returns

UIntPtr

The number of set bits in `value`.

Implements

PopCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.RotateLeft(UIntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value left by a given amount.

```
C#
public static UIntPtr RotateLeft (UIntPtr value, int rotateAmount);
```

Parameters

`value` UIntPtr

The value which is rotated left by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated left.

Returns

UIntPtr

The result of rotating `value` left by `rotateAmount`.

Implements

RotateLeft(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.RotateRight(UIntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Rotates a value right by a given amount.

```
C#
public static UIntPtr RotateRight (UIntPtr value, int rotateAmount);
```

Parameters

`value` UIntPtr

The value which is rotated right by `rotateAmount`.

`rotateAmount` Int32

The amount by which `value` is rotated right.

Returns

UIntPtr

The result of rotating `value` right by `rotateAmount`.

Implements

RotateRight(TSelf, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.Sign(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the sign of a value.

```
C#
public static int Sign (UIntPtr value);
```

Parameters

`value` UIntPtr

The value whose sign is to be computed.

Returns

Int32

A positive value if `value` is positive, Zero if `value` is zero, and a negative value if `value` is negative.

Implements

Sign(TSelf)

Remarks

It is recommended that a function return `1`, `0`, and `-1`, respectively.

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.Subtract(UIntPtr, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts an offset from an unsigned integer.

```
C#

public static UIntPtr Subtract (UIntPtr pointer, int offset);
```

Parameters

`pointer` UIntPtr

The unsigned integer to subtract the offset from.

`offset` Int32

The offset to subtract.

Returns

UIntPtr

A new unsigned integer that reflects the subtraction of `offset` from `pointer`.

Examples

The following example instantiates an IntPtr object that points to the end of a ten-element array, and then calls the Subtract method to iterate the elements in the array in reverse order.

```
C#

using System;

public class Example
{
   public static void Main()
```

```
    {
        int[] arr = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10};
        UIntPtr ptr = (UIntPtr) arr[arr.GetUpperBound(0)];
        for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++)
        {
            UIntPtr newPtr = UIntPtr.Subtract(ptr, ctr);
            Console.Write("{0}   ", newPtr);
        }
    }
}
// The example displays the following output:
//       10   9   8   7   6   5   4   3   2   1
```

Remarks

The Subtract method does not throw an exception if the result is too small to represent as an unsigned integer in the executing process. Instead, the subtraction operation is performed in an unchecked context.

Languages that do not support operator overloading or custom operators can use this method to subtract an offset from the value of a pointer.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr.ToPointer Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> Important
>
> This API is not CLS-compliant.

Converts the value of this instance to a pointer to an unspecified type.

```
C#
public void* ToPointer ();
```

Returns

Void*

A pointer to Void; that is, a pointer to memory containing data of an unspecified type.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

ToString()	Converts the numeric value of this instance to its equivalent string representation.
ToString(IFormatProvider)	Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.
ToString(String)	Converts the numeric value of this instance to its equivalent string representation, using the specified format.
ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.

ToString()

Converts the numeric value of this instance to its equivalent string representation.

C#

```
public override string ToString ();
```

Returns

String

The string representation of the value of this instance.

Remarks

If the value of the Size property for this instance is 4, then this method is equivalent to ToString; otherwise, this method is equivalent to ToString.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(IFormatProvider)

Converts the numeric value of this instance to its equivalent string representation using the specified format and culture-specific format information.

C#

```
public string ToString (IFormatProvider? provider);
```

Parameters

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The string representation of the value of this instance as specified by `provider`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToString(String)

Converts the numeric value of this instance to its equivalent string representation, using the specified format.

```
C#
public string ToString (string? format);
```

Parameters

`format` String

A standard or custom numeric format string.

Returns

String

The string representation of the value of this instance as specified by `format`.

Exceptions

FormatException

`format` is invalid or not supported.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

ToString(String, IFormatProvider)

Formats the value of the current instance using the specified format.

```
C#
public string ToString (string? format, IFormatProvider? provider);
```

Parameters

`format` String

The format to use. -or- A `null` reference (`Nothing` in Visual Basic) to use the default format defined for the type of the IFormattable implementation.

`provider` IFormatProvider

An object that supplies culture-specific formatting information.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Exceptions

FormatException

`format` is invalid or not supported.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

UIntPtr.ToUInt32 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to a 32-bit unsigned integer.

```
C#
public uint ToUInt32 ();
```

Returns

UInt32

A 32-bit unsigned integer equal to the value of this instance.

Exceptions

OverflowException

In a 64-bit process, the value of this instance is too large to represent as a 32-bit unsigned integer.

Remarks

An exception is only thrown if the value of `value` requires more bits than the executing process supports.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

UIntPtr.ToUInt64 Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of this instance to a 64-bit unsigned integer.

C#

```
public ulong ToUInt64 ();
```

Returns

UInt64

A 64-bit unsigned integer equal to the value of this instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr.TrailingZeroCount(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the number of trailing zeros in a value.

```
C#
public static UIntPtr TrailingZeroCount (UIntPtr value);
```

Parameters

`value` UIntPtr

The value whose trailing zeroes are to be counted.

Returns

UIntPtr

The number of trailing zeros in `value`.

Implements

TrailingZeroCount(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.
TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance into the provided span of characters.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten,
ReadOnlySpan<char> format = default, IFormatProvider? provider =
default);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

UIntPtr.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(String, IFormatProvider, UIntPtr)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Char>, UIntPtr)	Converts the read-only span of characters representation of a number to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(String, UIntPtr)	Converts the string representation of a number to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Byte>, IFormatProvider, UIntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, IFormatProvider, UIntPtr)	Tries to parse a string into a value.
TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UIntPtr)	Tries to parse a span of UTF-8 characters into a value.
TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UIntPtr)	Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Byte>, UIntPtr)	Tries to convert a UTF-8 character span containing the string representation of a number to its unsigned integer equivalent.
TryParse(String, NumberStyles, IFormatProvider, UIntPtr)	Converts the string representation of a number in a specified style and culture-specific format to its

	unsigned native integer equivalent. A return value indicates whether the conversion succeeded.

TryParse(String, IFormatProvider, UIntPtr)

Tries to parse a string into a value.

```
C#

public static bool TryParse (string? s, IFormatProvider? provider, out
UIntPtr result);
```

Parameters

`s` String

The string to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UIntPtr

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Char>, UIntPtr)

Converts the read-only span of characters representation of a number to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> s, out UIntPtr result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert.

`result` UIntPtr

When this method returns, contains the unsigned native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(String, UIntPtr)

Converts the string representation of a number to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.

```
C#
```

```
public static bool TryParse (string? s, out UIntPtr result);
```

Parameters

`s` String

A string containing a number to convert.

`result` UIntPtr

When this method returns, contains the unsigned native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

TryParse(ReadOnlySpan<Byte>, IFormatProvider, UIntPtr)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
IFormatProvider? provider, out UIntPtr result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UIntPtr

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, IFormatProvider, UIntPtr)

Tries to parse a string into a value.

C#

```
public static bool TryParse (ReadOnlySpan<char> s, IFormatProvider?
provider, out UIntPtr result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `s`.

`result` UIntPtr

When this method returns, contains the result of successfully parsing `s` or an undefined value on failure.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	7, 8, 9

TryParse(ReadOnlySpan<Byte>, NumberStyles, IFormatProvider, UIntPtr)

Tries to parse a span of UTF-8 characters into a value.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
UIntPtr result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

The span of UTF-8 characters to parse.

`style` NumberStyles

A bitwise combination of number styles that can be present in `utf8Text`.

`provider` IFormatProvider

An object that provides culture-specific formatting information about `utf8Text`.

`result` UIntPtr

On return, contains the result of successfully parsing `utf8Text` or an undefined value on failure.

Returns

Boolean

`true` if `utf8Text` was successfully parsed; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(ReadOnlySpan<Char>, NumberStyles, IFormatProvider, UIntPtr)

Converts the read-only span of characters representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.

C#

```
public static bool TryParse (ReadOnlySpan<char> s,
System.Globalization.NumberStyles style, IFormatProvider? provider, out
UIntPtr result);
```

Parameters

`s` ReadOnlySpan<Char>

A read-only span of characters containing a number to convert. The span is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UIntPtr

When this method returns, contains the unsigned native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryParse(ReadOnlySpan<Byte>, UIntPtr)

Tries to convert a UTF-8 character span containing the string representation of a number to its unsigned integer equivalent.

C#

```
public static bool TryParse (ReadOnlySpan<byte> utf8Text, out UIntPtr
result);
```

Parameters

`utf8Text` ReadOnlySpan<Byte>

A span containing the UTF-8 characters representing the number to convert.

`result` UIntPtr

When this method returns, contains the unsigned integer value equivalent to the number contained in `utf8Text` if the conversion succeeded, or zero if the conversion failed. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `utf8Text` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryParse(String, NumberStyles, IFormatProvider, UIntPtr)

Converts the string representation of a number in a specified style and culture-specific format to its unsigned native integer equivalent. A return value indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? s, System.Globalization.NumberStyles
style, IFormatProvider? provider, out UIntPtr result);
```

Parameters

`s` String

A string containing a number to convert. The string is interpreted using the style specified by `style`.

`style` NumberStyles

A bitwise combination of enumeration values that indicates the style elements that can be present in `s`.

`provider` IFormatProvider

An object that supplies culture-specific formatting information about `s`.

`result` UIntPtr

When this method returns, contains the unsigned native integer value equivalent of the number contained in `s`, if the conversion succeeded, or zero if the conversion failed. The conversion fails if the `s` parameter is `null` or empty, is not of the correct format, or represents a number less than MinValue or greater than MaxValue. This parameter is passed uninitialized; any value originally supplied in result will be overwritten.

Returns

Boolean

`true` if `s` was converted successfully; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	5, 6, 7, 8, 9

UIntPtr.Addition(UIntPtr, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds an offset to an unsigned integer.

C#

```
public static UIntPtr operator + (UIntPtr pointer, int offset);
```

Parameters

`pointer` UIntPtr

The unsigned integer to add the offset to.

`offset` Int32

The offset to add.

Returns

UIntPtr

A new unsigned integer that reflects the addition of `offset` to `pointer`.

Remarks

The Addition method defines the addition operation for UIntPtr objects. It enables code such as the following.

C#

```
int[] arr = {1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
UIntPtr ptr = (UIntPtr) arr[0];
for (int ctr = 0; ctr < arr.Length; ctr++)
{
```

```
    UIntPtr newPtr = ptr + ctr;
    Console.WriteLine(newPtr);
}
```

Languages that do not support custom operators can call the Add method instead.

The addition operation does not throw an exception if the result is too large to represent as an unsigned integer in the executing process. Instead, it is performed in an unchecked context.

In C# starting from version 11 and when targeting the .NET 7 or later runtime, this API is only accessible via reflection. The addition operator is directly recognized by the language and will follow the normal language behavior for addition operations, including overflowing in a `checked` context if the result is too large to represent.

The equivalent method for this operator is UIntPtr.Add(UIntPtr, Int32).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr.Equality(UIntPtr, UIntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of UIntPtr are equal.

```
C#
public static bool operator == (UIntPtr value1, UIntPtr value2);
```

Parameters

`value1` UIntPtr

The first unsigned integer to compare.

`value2` UIntPtr

The second unsigned integer to compare.

Returns

Boolean

`true` if `value1` equals `value2`; otherwise, `false`.

Implements

Equality(TSelf, TOther)

Remarks

The equivalent method for this operator is UIntPtr.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UIntPtr.Explicit Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Explicit(UInt32 to UIntPtr)	Converts the value of a 32-bit unsigned integer to an UIntPtr.
Explicit(UInt64 to UIntPtr)	Converts the value of a 64-bit unsigned integer to an UIntPtr.
Explicit(UIntPtr to UInt32)	Converts the value of the specified UIntPtr to a 32-bit unsigned integer.
Explicit(UIntPtr to UInt64)	Converts the value of the specified UIntPtr to a 64-bit unsigned integer.
Explicit(UIntPtr to Void*)	Converts the value of the specified UIntPtr to a pointer to an unspecified type. This API is not CLS-compliant.
Explicit(Void* to UIntPtr)	Converts the specified pointer to an unspecified type to an UIntPtr. This API is not CLS-compliant.

Explicit(UInt32 to UIntPtr)

Converts the value of a 32-bit unsigned integer to an UIntPtr.

C#

```
public static explicit operator UIntPtr (uint value);
```

Parameters

`value` UInt32

A 32-bit unsigned integer.

Returns

UIntPtr

A new instance of UIntPtr initialized to `value`.

See also

- UIntPtr

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Explicit(UInt64 to UIntPtr)

Converts the value of a 64-bit unsigned integer to an UIntPtr.

C#

```
public static explicit operator UIntPtr (ulong value);
```

Parameters

`value` UInt64

A 64-bit unsigned integer.

Returns

UIntPtr

A new instance of UIntPtr initialized to `value`.

Exceptions

OverflowException

In a 32-bit process, `value` is too large to represent as an UIntPtr.

See also

- UIntPtr

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Explicit(UIntPtr to UInt32)

Converts the value of the specified UIntPtr to a 32-bit unsigned integer.

C#

```
public static explicit operator uint (UIntPtr value);
```

Parameters

`value` UIntPtr

The unsigned integer to convert.

Returns

UInt32

The contents of `value`.

Exceptions

OverflowException

In a 64-bit process, the value of `value` is too large to represent as a 32-bit unsigned integer.

Remarks

An exception is only thrown if the value of `value` requires more bits than the executing process supports.

UIntPtr.Inequality(UIntPtr, UIntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified instances of UIntPtr are not equal.

```
C#
public static bool operator != (UIntPtr value1, UIntPtr value2);
```

Parameters

`value1` UIntPtr

The first unsigned integer to compare.

`value2` UIntPtr

The second unsigned integer to compare.

Returns

Boolean

`true` if `value1` does not equal `value2`; otherwise, `false`.

Implements

Inequality(TSelf, TOther)

Remarks

The equivalent method for this operator is UIntPtr.Equals(Object)

Applies to

Product	Versions

UIntPtr.Subtraction(UIntPtr, Int32) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts an offset from an unsigned integer.

```
C#

public static UIntPtr operator - (UIntPtr pointer, int offset);
```

Parameters

`pointer` UIntPtr

The unsigned integer to subtract the offset from.

`offset` Int32

The offset to subtract.

Returns

UIntPtr

A new unsigned integer that reflects the subtraction of `offset` from `pointer`.

Remarks

The Subtraction method defines the subtraction operation for UIntPtr objects. It enables code such as the following.

```
C#

int[] arr = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10};
UIntPtr ptr = (UIntPtr) arr[arr.GetUpperBound(0)];
for (int ctr = 0; ctr <= arr.GetUpperBound(0); ctr++)
{
```

```
    UIntPtr newPtr = ptr - ctr;
    Console.Write("{0}   ", newPtr);
}
```

Languages that do not support custom operators can call the Subtract method instead.

The subtraction operation does not throw an exception if the result is too small to represent as an unsigned integer in the executing process. Instead, it is performed in an unchecked context.

In C# starting from version 11 and when targeting the .NET 7 or later runtime, this API is only accessible via reflection. The subtraction operator is directly recognized by the language and will follow the normal language behavior for subtraction operations, including overflowing in a `checked` context if the result is too small to represent.

UIntPtr.IAdditionOperators<UIntPtr,UIntPtr,UIntPtr>.Addition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

```
C#

static UIntPtr IAdditionOperators<UIntPtr,UIntPtr,UIntPtr>.operator +
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to which `right` is added.

`right` UIntPtr

The value that's added to `left`.

Returns

UIntPtr

The sum of `left` and `right`.

Implements

Addition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IAdditionOperators<UIntPtr,UIntPtr,UIntPtr>.CheckedAddition Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Adds two values together to compute their sum.

C#

```
static UIntPtr
IAdditionOperators<UIntPtr,UIntPtr,UIntPtr>.op_CheckedAddition (UIntPtr
left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to which `right` is added.

`right` UIntPtr

The value that's added to `left`.

Returns

UIntPtr

The sum of `left` and `right`.

Implements

CheckedAddition(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IAdditiveIdentity<UIntPtr,UIntPtr>.AdditiveIdentity Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the additive identity of the current type.

C#

```
static UIntPtr
System.Numerics.IAdditiveIdentity<System.UIntPtr,System.UIntPtr>.AdditiveIde
ntity { get; }
```

Property Value

UIntPtr

Implements

AdditiveIdentity

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IBinaryInteger<UIntPtr>.GetByteCount Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).

C#

```
int IBinaryInteger<UIntPtr>.GetByteCount ();
```

Returns

Int32

The number of bytes that will be written as part of TryWriteLittleEndian(Span<Byte>, Int32).

Implements

GetByteCount()

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IBinaryInteger<UIntPtr>.GetShortestBitLength Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the length, in bits, of the shortest two's complement representation of the current value.

C#

```
int IBinaryInteger<UIntPtr>.GetShortestBitLength ();
```

Returns

Int32

The length, in bits, of the shortest two's complement representation of the current value.

Implements

GetShortestBitLength()

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IBinaryInteger<UIntPtr>.TryWriteBigEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in big-endian format, to a given span.

C#

```
bool IBinaryInteger<UIntPtr>.TryWriteBigEndian (Span<byte> destination, out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteBigEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IBinaryInteger<UIntPtr>.TryWriteLittleEndian Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to write the current value, in little-endian format, to a given span.

C#

```
bool IBinaryInteger<UIntPtr>.TryWriteLittleEndian (Span<byte> destination,
out int bytesWritten);
```

Parameters

destination Span<Byte>

The span to which the current value should be written.

bytesWritten Int32

When this method returns, contains the number of bytes written to `destination`.

Returns

Boolean

`true` if the value was succesfully written to `destination`; otherwise, `false`.

Implements

TryWriteLittleEndian(Span<Byte>, Int32)

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.BitwiseAnd Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-and of two values.

C#

```
static UIntPtr IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.operator &
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to `and` with `right`.

`right` UIntPtr

The value to `and` with `left`.

Returns

UIntPtr

The bitwise-and of `left` and `right`.

Implements

BitwiseAnd(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.BitwiseOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the bitwise-or of two values.

C#

```
static UIntPtr IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.operator |
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to `or` with `right`.

`right` UIntPtr

The value to `or` with `left`.

Returns

UIntPtr

The bitwise-or of `left` and `right`.

Implements

BitwiseOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.ExclusiveOr Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the exclusive-or of two values.

```
C#

static UIntPtr IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.operator ^
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to xor with `right`.

`right` UIntPtr

The value to xor with `left`.

Returns

UIntPtr

The exclusive-or of `left` and `right`.

Implements

ExclusiveOr(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.OnesComplement Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the ones-complement representation of a given value.

C#

```
static UIntPtr IBitwiseOperators<UIntPtr,UIntPtr,UIntPtr>.operator ~
(UIntPtr value);
```

Parameters

`value` UIntPtr

The value for which to compute the ones-complement.

Returns

UIntPtr

The ones-complement of `value`.

Implements

OnesComplement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IComparisonOperators<UIntPtr,UIntPtr,Boolean>.GreaterThanOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater.

```
C#

static bool IComparisonOperators<UIntPtr,UIntPtr,bool>.operator > (UIntPtr
left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to compare with `right`.

`right` UIntPtr

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than `right`; otherwise, `false`.

Implements

GreaterThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IComparisonOperators<UIntPtr,UIntPtr,Boolean>.GreaterThanOrEqual Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is greater or equal.

```
C#

static bool IComparisonOperators<UIntPtr,UIntPtr,bool>.operator >= (UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to compare with `right`.

`right` UIntPtr

The value to compare with `left`.

Returns

Boolean

`true` if `left` is greater than or equal to `right`; otherwise, `false`.

Implements

GreaterThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IComparisonOperators<UIntPtr,UIntPtr,Boolean>.LessThan Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less.

```
C#

static bool IComparisonOperators<UIntPtr,UIntPtr,bool>.operator < (UIntPtr
left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to compare with `right`.

`right` UIntPtr

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than `right`; otherwise, `false`.

Implements

LessThan(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.IComparisonOperators<UIntPtr,UIntPtr,Boolean>.LessThanOrEqualOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to determine which is less or equal.

```
C#

static bool IComparisonOperators<UIntPtr,UIntPtr,bool>.operator <= (UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value to compare with `right`.

`right` UIntPtr

The value to compare with `left`.

Returns

Boolean

`true` if `left` is less than or equal to `right`; otherwise, `false`.

Implements

LessThanOrEqual(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IDecrementOperators<UIntPtr>.CheckedDecrement(UIntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Decrements a value.

```
C#

static UIntPtr IDecrementOperators<UIntPtr>.op_CheckedDecrement (UIntPtr
value);
```

Parameters

`value` UIntPtr

The value to decrement.

Returns

UIntPtr

The result of decrementing `value`.

Implements

CheckedDecrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IDivisionOperators<UIntPtr,UIntPtr,UIntPtr>.Division Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides one value by another to compute their quotient.

```
C#

static UIntPtr IDivisionOperators<UIntPtr,UIntPtr,UIntPtr>.operator /
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value that `right` divides.

`right` UIntPtr

The value that divides `left`.

Returns

UIntPtr

The quotient of `left` divided by `right`.

Implements

Division(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IIncrementOperators<UIntPtr>.CheckedIncrement(UIntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Increments a value.

```
C#

static UIntPtr IIncrementOperators<UIntPtr>.op_CheckedIncrement (UIntPtr
value);
```

Parameters

`value` UIntPtr

The value to increment.

Returns

UIntPtr

The result of incrementing `value`.

Implements

CheckedIncrement(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IModulusOperators<UIntPtr,UIntPtr,UIntPtr>.Modulus Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Divides two values together to compute their modulus or remainder.

```
C#

static UIntPtr IModulusOperators<UIntPtr,UIntPtr,UIntPtr>.operator %
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value that `right` divides.

`right` UIntPtr

The value that divides `left`.

Returns

UIntPtr

The modulus or remainder of `left` divided by `right`.

Implements

Modulus(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IMultiplyOperators<UIntPtr,UIntPtr,UIntPtr>.CheckedMultiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

C#

```
static UIntPtr
IMultiplyOperators<UIntPtr,UIntPtr,UIntPtr>.op_CheckedMultiply (UIntPtr
left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value that `right` multiplies.

`right` UIntPtr

The value that multiplies `left`.

Returns

UIntPtr

The product of `left` multiplied by `right`.

Implements

CheckedMultiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IMultiplyOperators<UIntPtr,UIntPtr,UIntPtr>.Multiply Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Multiplies two values together to compute their product.

```
C#

static UIntPtr IMultiplyOperators<UIntPtr,UIntPtr,UIntPtr>.operator *
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value that `right` multiplies.

`right` UIntPtr

The value that multiplies `left`.

Returns

UIntPtr

The product of `left` multiplied by `right`.

Implements

Multiply(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumber<UIntPtr>.CopySign(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Copies the sign of a value to the sign of another value.

C#

```
static UIntPtr INumber<UIntPtr>.CopySign (UIntPtr value, UIntPtr sign);
```

Parameters

`value` UIntPtr

The value whose magnitude is used in the result.

`sign` UIntPtr

The value whose sign is used in the result.

Returns

UIntPtr

A value with the magnitude of `value` and the sign of `sign`.

Implements

CopySign(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumber<UIntPtr>.MinNumber(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser and returning the other value if an input is `NaN`.

```
C#
static UIntPtr INumber<UIntPtr>.MinNumber (UIntPtr x, UIntPtr y);
```

Parameters

x UIntPtr

The value to compare with `y`.

y UIntPtr

The value to compare with `x`.

Returns

UIntPtr

`x` if it is less than `y`; otherwise, `y`.

Implements

MinNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.Abs(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the absolute of a value.

```
C#
static UIntPtr INumberBase<UIntPtr>.Abs (UIntPtr value);
```

Parameters

`value` UIntPtr

The value for which to get its absolute.

Returns

UIntPtr

The absolute of `value`.

Implements

Abs(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.IsCanonical(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is in its canonical representation.

C#

```
static bool INumberBase<UIntPtr>.IsCanonical (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is in its canonical representation; otherwise, `false`.

Implements

IsCanonical(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.IsComplexNumber(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a complex number.

C#

```
static bool INumberBase<UIntPtr>.IsComplexNumber (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a complex number; otherwise, `false`.

Implements

IsComplexNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.IsFinite(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is finite.

```
C#
static bool INumberBase<UIntPtr>.IsFinite (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is finite; otherwise, `false`.

Implements

IsFinite(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.IsImaginaryNumber(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a pure imaginary number.

C#

```
static bool INumberBase<UIntPtr>.IsImaginaryNumber (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a pure imaginary number; otherwise, `false`.

Implements

IsImaginaryNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.IsInfinity(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is infinite.

```
C#
static bool INumberBase<UIntPtr>.IsInfinity (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is infinite; otherwise, `false`.

Implements

IsInfinity(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.IsInteger(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents an integral number.

```
C#
static bool INumberBase<UIntPtr>.IsInteger (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is an integer; otherwise, `false`.

Implements

IsInteger(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.IsNaN(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is NaN.

```
C#
static bool INumberBase<UIntPtr>.IsNaN (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is NaN; otherwise, `false`.

Implements

IsNaN(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.IsNegative(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is negative.

```
C#
static bool INumberBase<UIntPtr>.IsNegative (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is negative; otherwise, `false`.

Implements

IsNegative(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.IsNormal(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is normal.

```
C#
static bool INumberBase<UIntPtr>.IsNormal (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is normal; otherwise, `false`.

Implements

IsNormal(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.IsPositive(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value is positive.

C#

```
static bool INumberBase<UIntPtr>.IsPositive (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is positive; otherwise, `false`.

Implements

IsPositive(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.IsRealNumber(UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines if a value represents a real number.

C#

```
static bool INumberBase<UIntPtr>.IsRealNumber (UIntPtr value);
```

Parameters

`value` UIntPtr

The value to be checked.

Returns

Boolean

`true` if `value` is a real number; otherwise, `false`.

Implements

IsRealNumber(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.MaxMagnitude(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is greater.

C#

```
static UIntPtr INumberBase<UIntPtr>.MaxMagnitude (UIntPtr x, UIntPtr y);
```

Parameters

x UIntPtr

The value to compare with `y`.

y UIntPtr

The value to compare with `x`.

Returns

UIntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.MaxMagnitudeNumber Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which has the greater magnitude and returning the other value if an input is `NaN`.

C#

```
static UIntPtr INumberBase<UIntPtr>.MaxMagnitudeNumber (UIntPtr x, UIntPtr y);
```

Parameters

x UIntPtr

The value to compare with `y`.

y UIntPtr

The value to compare with `x`.

Returns

UIntPtr

`x` if it is greater than `y`; otherwise, `y`.

Implements

MaxMagnitudeNumber(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.MinMagnitude(UIntPtr, UIntPtr) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two values to compute which is lesser.

C#

```
static UIntPtr INumberBase<UIntPtr>.MinMagnitude (UIntPtr x, UIntPtr y);
```

Parameters

x UIntPtr

The value to compare with `y`.

y UIntPtr

The value to compare with `x`.

Returns

UIntPtr

`x` if it is less than `y`; otherwise, `y`.

Implements

MinMagnitude(TSelf, TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.TryConvertToChecked<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, throwing an overflow exception for any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<UIntPtr>.TryConvertToChecked<TOther> (UIntPtr value,
out TOther result) where TOther : System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UIntPtr

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToChecked<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

The source for this content can be found on GitHub, where you can also create and review issues and pull requests. For more information, see our contributor guide.

UIntPtr.INumberBase<UIntPtr>.TryConvertToSaturating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, saturating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<UIntPtr>.TryConvertToSaturating<TOther> (UIntPtr
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UIntPtr

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToSaturating<TOther>(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.INumberBase<UIntPtr>.TryConvertToTruncating<TOther> Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to convert an instance of the the current type to another type, truncating any values that fall outside the representable range of the current type.

```
C#

static bool INumberBase<UIntPtr>.TryConvertToTruncating<TOther> (UIntPtr
value, out TOther result) where TOther :
System.Numerics.INumberBase<TOther>;
```

Type Parameters

`TOther`

The type to which `value` should be converted.

Parameters

`value` UIntPtr

The value that's used to create the instance of `TOther`.

`result` TOther

When this method returns, contains an instance of `TOther` converted from `value`.

Returns

Boolean

`false` if `TOther` is not supported; otherwise, `true`.

Implements

TryConvertToTruncating<TOther>(TSelf, TOther)

UIntPtr.IShiftOperators<UIntPtr,Int32,UIntPtr>.LeftShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value left by a given amount.

C#

```
static UIntPtr IShiftOperators<UIntPtr,int,UIntPtr>.operator << (UIntPtr
value, int shiftAmount);
```

Parameters

value UIntPtr

The value that is shifted left by `shiftAmount`.

shiftAmount Int32

The amount by which `value` is shifted left.

Returns

UIntPtr

The result of shifting `value` left by `shiftAmount`.

Implements

LeftShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IShiftOperators<UIntPtr,Int32,UIntPtr>.RightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

C#

```
static UIntPtr IShiftOperators<UIntPtr,int,UIntPtr>.operator >> (UIntPtr
value, int shiftAmount);
```

Parameters

value UIntPtr

The value that is shifted right by `shiftAmount`.

shiftAmount Int32

The amount by which `value` is shifted right.

Returns

UIntPtr

The result of shifting `value` right by `shiftAmount`.

Implements

RightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IShiftOperators<UIntPtr,Int32,UIntPtr>.UnsignedRightShift Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Shifts a value right by a given amount.

```
C#

static UIntPtr IShiftOperators<UIntPtr,int,UIntPtr>.op_UnsignedRightShift
(UIntPtr value, int shiftAmount);
```

Parameters

`value` UIntPtr

The value that is shifted right by `shiftAmount`.

`shiftAmount` Int32

The amount by which `value` is shifted right.

Returns

UIntPtr

The result of shifting `value` right by `shiftAmount`.

Implements

UnsignedRightShift(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.ISubtractionOperators<UIntPtr,UIntPtr,UIntPtr>.CheckedSubtractionOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

C#

```
static UIntPtr
ISubtractionOperators<UIntPtr,UIntPtr,UIntPtr>.op_CheckedSubtraction
(UIntPtr left, UIntPtr right);
```

Parameters

left UIntPtr

The value from which `right` is subtracted.

right UIntPtr

The value that's subtracted from `left`.

Returns

UIntPtr

The value of `right` subtracted from `left`.

Implements

CheckedSubtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

Namespace: System

Assembly: System.Runtime.dll

Subtracts two values to compute their difference.

```
C#

static UIntPtr ISubtractionOperators<UIntPtr,UIntPtr,UIntPtr>.operator -
(UIntPtr left, UIntPtr right);
```

Parameters

`left` UIntPtr

The value from which `right` is subtracted.

`right` UIntPtr

The value that's subtracted from `left`.

Returns

UIntPtr

The value of `right` subtracted from `left`.

Implements

Subtraction(TSelf, TOther)

Applies to

Product	Versions
.NET	7, 8, 9

UIntPtr.IUnaryNegationOperators<UIntPtr,UIntPtr>.CheckedUnaryNegationOperator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the checked unary negation of a value.

```
C#

static UIntPtr
IUnaryNegationOperators<UIntPtr,UIntPtr>.op_CheckedUnaryNegation (UIntPtr
value);
```

Parameters

`value` UIntPtr

The value for which to compute the unary negation.

Returns

UIntPtr

The unary negation of `value`.

Implements

CheckedUnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IUnaryNegationOperators<UIntPtr,UIntPtr>.UnaryNegation Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary negation of a value.

```
C#

static UIntPtr IUnaryNegationOperators<UIntPtr,UIntPtr>.operator - (UIntPtr
value);
```

Parameters

`value` UIntPtr

The value for which to compute the unary negation.

Returns

UIntPtr

The unary negation of `value`.

Implements

UnaryNegation(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.IUnaryPlusOperators<UIntPtr,UIntPtr>.UnaryPlus(UIntPtr) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Computes the unary plus of a value.

```
C#

static UIntPtr IUnaryPlusOperators<UIntPtr,UIntPtr>.operator + (UIntPtr
value);
```

Parameters

`value` UIntPtr

The value for which to compute the unary plus.

Returns

UIntPtr

The unary plus of `value`.

Implements

UnaryPlus(TSelf)

Applies to

Product	Versions
.NET	7, 8, 9

Collaborate with us on GitHub

UIntPtr.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo object with the data needed to serialize the current UIntPtr object.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo object to populate with data.

`context` StreamingContext

The destination for this serialization. (This parameter is not used; specify `null`.)

Implements

GetObjectData(SerializationInfo, StreamingContext)

Exceptions

ArgumentNullException

`info` is `null`.

Remarks

This method populates the `info` parameter with the value of the current UIntPtr object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UnauthorizedAccessException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when the operating system denies access because of an I/O error or a specific type of security error.

C#

```
public class UnauthorizedAccessException : SystemException
```

Inheritance Object → Exception → SystemException → UnauthorizedAccessException

Derived System.Security.AccessControl.PrivilegeNotHeldException

Examples

The following example illustrates the UnauthorizedAccessException exception that is thrown when attempting to write to a read-only file.

C#

```
using System;
using System.IO;

public class Example
{
   public static void Main()
   {
      string filePath = @".\ROFile.txt";
      if (! File.Exists(filePath))
         File.Create(filePath);
      // Keep existing attributes, and set ReadOnly attribute.
      File.SetAttributes(filePath,
                         (new FileInfo(filePath)).Attributes |
FileAttributes.ReadOnly);

      StreamWriter sw = null;
      try {
         sw = new StreamWriter(filePath);
```

```
            sw.Write("Test");
        }
        catch (UnauthorizedAccessException) {
            FileAttributes attr = (new FileInfo(filePath)).Attributes;
            Console.Write("UnAuthorizedAccessException: Unable to access file.
");
            if ((attr & FileAttributes.ReadOnly) > 0)
                Console.Write("The file is read-only.");
         }
         finally {
            if (sw != null) sw.Close();
        }
    }
}
// The example displays the following output:
//    UnAuthorizedAccessException: Unable to access file. The file is read-
only.
```

Remarks

An UnauthorizedAccessException exception is typically thrown by a method that wraps a Windows API call. To find the reasons for the exception, examine the text of the exception object's Message property.

UnauthorizedAccessException uses the `HRESULT` `COR_E_UNAUTHORIZEDACCESS`, which has the value 0x80070005.

Constructors

Expand table

UnauthorizedAccessException()	Initializes a new instance of the UnauthorizedAccessException class.
UnauthorizedAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the UnauthorizedAccessException class with serialized data.
UnauthorizedAccessException(String)	Initializes a new instance of the UnauthorizedAccessException class with a specified error message.
UnauthorizedAccessException(String, Exception)	Initializes a new instance of the UnauthorizedAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.**

	When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UnauthorizedAccessException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the UnauthorizedAccessException class.

Overloads

Expand table

UnauthorizedAccessException()	Initializes a new instance of the UnauthorizedAccessException class.
UnauthorizedAccessException(String)	Initializes a new instance of the UnauthorizedAccessException class with a specified error message.
UnauthorizedAccessException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the UnauthorizedAccessException class with serialized data.
UnauthorizedAccessException(String, Exception)	Initializes a new instance of the UnauthorizedAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

UnauthorizedAccessException()

Initializes a new instance of the UnauthorizedAccessException class.

C#

```
public UnauthorizedAccessException ();
```

Remarks

This constructor initializes the Message property of the new instance to a system-supplied message that describes the error, such as "Attempted to perform an unauthorized operation." This message takes into account the current system culture.

The following table shows the initial property values for an instance of MemberAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The localized error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UnauthorizedAccessException(String)

Initializes a new instance of the UnauthorizedAccessException class with a specified error message.

C#

```
public UnauthorizedAccessException (string? message);
```

Parameters

`message` String

The message that describes the error.

Remarks

The content of the `message` parameter should be understandable to the user. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

The following table shows the initial property values for an instance of UnauthorizedAccessException.

Expand table

Property	Value
InnerException	A null reference (`Nothing` in Visual Basic).
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UnauthorizedAccessException(SerializationInfo, StreamingContext)

⊗ **Caution**

This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the UnauthorizedAccessException class with serialized data.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected UnauthorizedAccessException
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

The SerializationInfo that holds the serialized object data about the exception being thrown.

`context` StreamingContext

The StreamingContext that contains contextual information about the source or destination.

Attributes ObsoleteAttribute

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UnauthorizedAccessException(String, Exception)

Initializes a new instance of the UnauthorizedAccessException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
C#

public UnauthorizedAccessException (string? message, Exception? inner);
```

Parameters

`message` String

The error message that explains the reason for the exception.

`inner` Exception

The exception that is the cause of the current exception. If the `inner` parameter is not a null reference (`Nothing` in Visual Basic), the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or a null reference (`Nothing` in Visual Basic) if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of UnauthorizedAccessException.

Expand table

Property	Value
InnerException	The inner exception reference.
Message	The error message string.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UnhandledExceptionEventArgs Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides data for the event that is raised when there is an exception that is not handled in any application domain.

C#

```
public class UnhandledExceptionEventArgs : EventArgs
```

Inheritance Object → EventArgs → UnhandledExceptionEventArgs

Remarks

UnhandledExceptionEventArgs provides access to the exception object and a flag indicating whether the common language runtime is terminating. The UnhandledExceptionEventArgs is one of the parameters passed into UnhandledExceptionEventHandler for the AppDomain.UnhandledException event.

For more information about event handler delegates, see Handling and Raising Events.

Constructors

Expand table

UnhandledExceptionEventArgs(Object, Boolean)	Initializes a new instance of the UnhandledExceptionEventArgs class with the exception object and a common language runtime termination flag.

Properties

Expand table

Exception Object	Gets the unhandled exception object.
IsTerminating	Gets a value that indicates whether the common language runtime is terminating.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UnhandledExceptionEventArgs(Object, Boolean) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the UnhandledExceptionEventArgs class with the exception object and a common language runtime termination flag.

C#

```
public UnhandledExceptionEventArgs (object exception, bool isTerminating);
```

Parameters

`exception` Object

The exception that is not handled.

`isTerminating` Boolean

`true` if the runtime is terminating; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UnhandledExceptionEventArgs.ExceptionObject Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the unhandled exception object.

C#

```
public object ExceptionObject { get; }
```

Property Value

Object

The unhandled exception object.

Examples

The following example demonstrates the UnhandledException event. It defines an event handler, `MyHandler`, that is invoked whenever an unhandled exception is thrown in the default application domain. It then throws two exceptions. The first is handled by a **try/catch** block. The second is unhandled and invokes the `MyHandle` routine before the application terminates.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      AppDomain currentDomain = AppDomain.CurrentDomain;
      currentDomain.UnhandledException += new
UnhandledExceptionEventHandler(MyHandler);

      try {
```

```
            throw new Exception("1");
        } catch (Exception e) {
            Console.WriteLine("Catch clause caught : {0} \n", e.Message);
        }

        throw new Exception("2");
    }

    static void MyHandler(object sender, UnhandledExceptionEventArgs args)
    {
        Exception e = (Exception) args.ExceptionObject;
        Console.WriteLine("MyHandler caught : " + e.Message);
        Console.WriteLine("Runtime terminating: {0}", args.IsTerminating);
    }
}
// The example displays the following output:
//       Catch clause caught : 1
//
//       MyHandler caught : 2
//       Runtime terminating: True
//
//       Unhandled Exception: System.Exception: 2
//          at Example.Main()
```

Remarks

This property returns an object of type Object rather than one derived from Exception. Although the Common Language Specification requires that all exception types derive from Exception, it is possible for methods to throw exceptions with objects not derived from Exception. You can do the following to work with this exception:

- Apply the RuntimeCompatibilityAttribute attribute with a RuntimeCompatibilityAttribute.WrapNonExceptionThrows value of `true` to the assembly that contains the event handler. This wraps all exceptions not derived from the Exception class in a RuntimeWrappedException object. You can then safely cast (in C#) or convert (in Visual Basic) the object returned by this property to an Exception object, and retrieve the original exception object from the RuntimeWrappedException.WrappedException property. Note that some compilers, such as the C# and Visual Basic compilers, automatically apply this attribute.

- Cast the object returned by this property to an Exception object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UnhandledExceptionEventArgs.IsTerminating Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the common language runtime is terminating.

```
C#
public bool IsTerminating { get; }
```

Property Value

Boolean

`true` if the runtime is terminating; otherwise, `false`.

Remarks

This property returns `true` for most unhandled exceptions. The reason is that most unhandled exceptions in threads, including thread pool threads, are allowed to proceed naturally, which normally results in termination of the application. For more information, including a list of cases in which the runtime does not terminate, see Exceptions in Managed Threads.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UnhandledExceptionEventHandler Delegate

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the method that will handle the event raised by an exception that is not handled by the application domain.

C#

```
public delegate void UnhandledExceptionEventHandler(object sender,
UnhandledExceptionEventArgs e);
```

Parameters

sender Object

The source of the unhandled exception event.

e UnhandledExceptionEventArgs

An `UnhandledExceptionEventArgs` that contains the event data.

Remarks

An UnhandledExceptionEventHandler can only be specified for the default application domain that is created by the system to execute an application. Specifying an UnhandledExceptionEventHandler for an AppDomain created by an application has no effect.

When you create an UnhandledExceptionEventHandler delegate, you identify the method that will handle the event. To associate the event handler with your event, add an instance of the delegate to the event. The event handler is called whenever the event occurs, unless you remove the delegate. For more information about event handler delegates, see Handling and Raising Events.

Extension Methods

Expand table

GetMethodInfo(Delegate)	Gets an object that represents the method represented by the specified delegate.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Uri Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides an object representation of a uniform resource identifier (URI) and easy access to the parts of the URI.

```C#
public class Uri : ISpanFormattable,
System.Runtime.Serialization.ISerializable
```

Inheritance Object → Uri

Implements ISerializable , IFormattable , ISpanFormattable

Examples

The following example creates an instance of the Uri class and uses it to perform a GET request with HttpClient.

```C#
Uri siteUri = new Uri("http://www.contoso.com/");

// HttpClient lifecycle management best practices:
//
https://learn.microsoft.com/dotnet/fundamentals/networking/http/httpclient-
guidelines#recommended-use
HttpClient client = new HttpClient();
HttpRequestMessage request = new HttpRequestMessage(HttpMethod.Get,
siteUri);
HttpResponseMessage response = client.Send(request);
```

The following code snippet shows example values of the various properties on the class.

```C#
```

```
Uri uri = new Uri("https://user:password@www.contoso.com:80/Home/Index.htm?
q1=v1&q2=v2#FragmentName");

Console.WriteLine($"AbsolutePath: {uri.AbsolutePath}");
Console.WriteLine($"AbsoluteUri: {uri.AbsoluteUri}");
Console.WriteLine($"DnsSafeHost: {uri.DnsSafeHost}");
Console.WriteLine($"Fragment: {uri.Fragment}");
Console.WriteLine($"Host: {uri.Host}");
Console.WriteLine($"HostNameType: {uri.HostNameType}");
Console.WriteLine($"IdnHost: {uri.IdnHost}");
Console.WriteLine($"IsAbsoluteUri: {uri.IsAbsoluteUri}");
Console.WriteLine($"IsDefaultPort: {uri.IsDefaultPort}");

Remarks

For more information about this API, see Supplemental API remarks for Uri.

Constructors

Expand table

Uri(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the Uri class from the specified instances of the SerializationInfo and StreamingContext classes.
Uri(String)	Initializes a new instance of the Uri class with the specified URI.
Uri(String, Boolean)	**Obsolete.** Initializes a new instance of the Uri class with the specified URI, with explicit control of character escaping.
Uri(String, UriCreationOptions)	Initializes a new instance of the Uri class with the specified URI and additional UriCreationOptions.
Uri(String, UriKind)	Initializes a new instance of the Uri class with the specified URI. This constructor allows you to specify if the URI string is a relative URI, absolute URI, or is indeterminate.
Uri(Uri, String)	Initializes a new instance of the Uri class based on the specified base URI and relative URI string.
Uri(Uri, String, Boolean)	**Obsolete.** Initializes a new instance of the Uri class based on the specified base and relative URIs, with explicit control of character escaping.
Uri(Uri, Uri)	Initializes a new instance of the Uri class based on the combination of a specified base Uri instance and a relative Uri instance.

Fields

Expand table

SchemeDelimiter	Specifies the characters that separate the communication protocol scheme from the address portion of the URI. This field is read-only.
UriSchemeFile	Specifies that the URI is a pointer to a file. This field is read-only.
UriSchemeFtp	Specifies that the URI is accessed through the File Transfer Protocol (FTP). This field is read-only.

UriScheme Ftps	Specifies that the URI is accessed through the File Transfer Protocol Secure (FTPS). This field is read-only.
UriScheme Gopher	Specifies that the URI is accessed through the Gopher protocol. This field is read-only.
UriScheme Http	Specifies that the URI is accessed through the Hypertext Transfer Protocol (HTTP). This field is read-only.
UriScheme Https	Specifies that the URI is accessed through the Secure Hypertext Transfer Protocol (HTTPS). This field is read-only.
UriScheme Mailto	Specifies that the URI is an email address and is accessed through the Simple Mail Transport Protocol (SMTP). This field is read-only.
UriSchemeNet Pipe	Specifies that the URI is accessed through the NetPipe scheme used by Windows Communication Foundation (WCF). This field is read-only.
UriSchemeNet Tcp	Specifies that the URI is accessed through the NetTcp scheme used by Windows Communication Foundation (WCF). This field is read-only.
UriScheme News	Specifies that the URI is an Internet news group and is accessed through the Network News Transport Protocol (NNTP). This field is read-only.
UriScheme Nntp	Specifies that the URI is an Internet news group and is accessed through the Network News Transport Protocol (NNTP). This field is read-only.
UriScheme Sftp	Specifies that the URI is accessed through the SSH File Transfer Protocol (SFTP). This field is read-only.
UriSchemeSsh	Specifies that the URI is accessed through the Secure Socket Shell protocol (SSH). This field is read-only.
UriScheme Telnet	Specifies that the URI is accessed through the Telnet protocol. This field is read-only.
UriSchemeWs	Specifies that the URI is accessed through the WebSocket protocol (WS). This field is read-only.
UriScheme Wss	Specifies that the URI is accessed through the WebSocket Secure protocol (WSS). This field is read-only.

Properties

Expand table

Absolute Path	Gets the absolute path of the URI.

AbsoluteUri	Gets the absolute URI.
Authority	Gets the Domain Name System (DNS) host name or IP address and the port number for a server.
DnsSafe Host	Gets a host name that, after being unescaped if necessary, is safe to use for DNS resolution.
Fragment	Gets the escaped URI fragment, including the leading '#' character if not empty.
Host	Gets the host component of this instance.
HostName Type	Gets the type of the host name specified in the URI.
IdnHost	Gets the RFC 3490 compliant International Domain Name of the host, using Punycode as appropriate. This string, after being unescaped if necessary, is safe to use for DNS resolution.
IsAbsolute Uri	Gets a value that indicates whether the Uri instance is absolute.
IsDefault Port	Gets a value that indicates whether the port value of the URI is the default for this scheme.
IsFile	Gets a value that indicates whether the specified Uri is a file URI.
IsLoopback	Gets a value that indicates whether the specified Uri references the local host.
IsUnc	Gets a value that indicates whether the specified Uri is a universal naming convention (UNC) path.
LocalPath	Gets a local operating-system representation of a file name.
Original String	Gets the original URI string that was passed to the Uri constructor.
PathAnd Query	Gets the AbsolutePath and Query properties separated by a question mark (?).
Port	Gets the port number of this URI.
Query	Gets any query information included in the specified URI, including the leading '?' character if not empty.
Scheme	Gets the scheme name for this URI.
Segments	Gets an array containing the path segments that make up the specified URI.
User Escaped	Gets a value that indicates whether the URI string was completely escaped before the Uri instance was created.

UserInfo	Gets the user name, password, or other user-specific information associated with the specified URI.

Methods

Expand table

Canonicalize()	**Obsolete.** Converts the internally stored URI to canonical form.
CheckHostName(String)	Determines whether the specified host name is a valid DNS name.
CheckSchemeName(String)	Determines whether the specified scheme name is valid.
CheckSecurity()	**Obsolete.** Calling this method has no effect.
Compare(Uri, Uri, UriComponents, UriFormat, StringComparison)	Compares the specified parts of two URIs using the specified comparison rules.
Equals(Object)	Compares two Uri instances for equality.
Escape()	**Obsolete.** Converts any unsafe or reserved characters in the path component to their hexadecimal character representations.
EscapeDataString(String)	Converts a string to its escaped representation.
EscapeString(String)	**Obsolete.** Converts a string to its escaped representation.
EscapeUriString(String)	**Obsolete.** Converts a URI string to its escaped representation.
FromHex(Char)	Gets the decimal value of a hexadecimal digit.
GetComponents(UriComponents, UriFormat)	Gets the specified components of the current instance using the specified escaping for special characters.
GetHashCode()	Gets the hash code for the URI.
GetLeftPart(UriPartial)	Gets the specified portion of a Uri instance.

GetObjectData(SerializationInfo, StreamingContext)	Returns the data needed to serialize the current instance.
GetType()	Gets the Type of the current instance. (Inherited from Object)
HexEscape(Char)	Converts a specified character into its hexadecimal equivalent.
HexUnescape(String, Int32)	Converts a specified hexadecimal representation of a character to the character.
IsBadFileSystemCharacter(Char)	**Obsolete.** Indicates whether a character is invalid in a file system name.
IsBaseOf(Uri)	Determines whether the current Uri instance is a base of the specified Uri instance.
IsExcludedCharacter(Char)	**Obsolete.** Determines whether the specified character should be escaped.
IsHexDigit(Char)	Determines whether a specified character is a valid hexadecimal digit.
IsHexEncoding(String, Int32)	Determines whether a character in a string is hexadecimal encoded.
IsReservedCharacter(Char)	**Obsolete.** Determines whether the specified character is a reserved character.
IsWellFormedOriginalString()	Indicates whether the string used to construct this Uri was well-formed and does not require further escaping.
IsWellFormedUriString(String, UriKind)	Indicates whether the string is well-formed by attempting to construct a URI with the string and ensures that the string does not require further escaping.
MakeRelative(Uri)	**Obsolete.** Determines the difference between two Uri instances.
MakeRelativeUri(Uri)	Determines the difference between two Uri instances.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Parse()	**Obsolete.**

	Parses the URI of the current instance to ensure it contains all the parts required for a valid URI.
ToString()	Gets a canonical string representation for the specified Uri instance.
TryCreate(String, UriCreationOptions, Uri)	Creates a new Uri using the specified String instance and UriCreationOptions.
TryCreate(String, UriKind, Uri)	Creates a new Uri using the specified String instance and a UriKind.
TryCreate(Uri, String, Uri)	Creates a new Uri using the specified base and relative String instances.
TryCreate(Uri, Uri, Uri)	Creates a new Uri using the specified base and relative Uri instances.
TryFormat(Span<Char>, Int32)	Attempts to format a canonical string representation for the Uri instance into the specified span.
Unescape(String)	**Obsolete.** Converts the specified string by replacing any escape sequences with their unescaped representation.
UnescapeDataString(String)	Converts a string to its unescaped representation.

Operators

Expand table

Equality(Uri, Uri)	Determines whether two Uri instances have the same value.
Inequality(Uri, Uri)	Determines whether two Uri instances do not have the same value.

Explicit Interface Implementations

Expand table

IFormattable.ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.
ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Returns the data needed to serialize the current instance.

ISpanFormattable.TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.

Uri Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Uri class.

Overloads

Expand table

Uri(String)	Initializes a new instance of the Uri class with the specified URI.
Uri(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the Uri class from the specified instances of the SerializationInfo and StreamingContext classes.
Uri(String, Boolean)	**Obsolete.** Initializes a new instance of the Uri class with the specified URI, with explicit control of character escaping.
Uri(String, UriCreationOptions)	Initializes a new instance of the Uri class with the specified URI and additional UriCreationOptions.
Uri(String, UriKind)	Initializes a new instance of the Uri class with the specified URI. This constructor allows you to specify if the URI string is a relative URI, absolute URI, or is indeterminate.
Uri(Uri, String)	Initializes a new instance of the Uri class based on the specified base URI and relative URI string.
Uri(Uri, Uri)	Initializes a new instance of the Uri class based on the combination of a specified base Uri instance and a relative Uri instance.
Uri(Uri, String, Boolean)	**Obsolete.** Initializes a new instance of the Uri class based on the specified base and relative URIs, with explicit control of character escaping.

Uri(String)

Initializes a new instance of the Uri class with the specified URI.

```
C#

public Uri (string uriString);
```

Parameters

`uriString` String

A string that identifies the resource to be represented by the Uri instance. Note that an IPv6 address in string form must be enclosed within brackets. For example, "http://[2607:f8b0:400d:c06::69]".

Exceptions

ArgumentNullException

`uriString` is `null`.

UriFormatException

Note: In the .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

`uriString` is empty.

-or-

The scheme specified in `uriString` is not correctly formed. See CheckSchemeName(String).

-or-

`uriString` contains too many slashes.

-or-

The password specified in `uriString` is not valid.

-or-

The host name specified in `uriString` is not valid.

-or-

The file name specified in `uriString` is not valid.

-or-

The user name specified in `uriString` is not valid.

-or-

The host or authority name specified in `uriString` cannot be terminated by backslashes.

-or-

The port number specified in `uriString` is not valid or cannot be parsed.

-or-

The length of `uriString` exceeds 65519 characters.

-or-

The length of the scheme specified in `uriString` exceeds 1023 characters.

-or-

There is an invalid character sequence in `uriString`.

-or-

The MS-DOS path specified in `uriString` must start with c:\\.

Examples

The following example creates a Uri instance with the URI `http://www.contoso.com/`.

```
C#

Uri myUri = new Uri("http://www.contoso.com/");
```

Remarks

This constructor creates a Uri instance from a URI string. It parses the URI, puts it in canonical format, and makes any required escape encodings.

This constructor does not ensure that the Uri refers to an accessible resource.

This constructor assumes that the `string` parameter references an absolute URI and is equivalent to calling the Uri constructor with UriKind set to Absolute. If the `string` parameter passed to the constructor is a relative URI, this constructor will throw a UriFormatException.

Applies to

UWP	10.0

Uri(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the Uri class from the specified instances of the SerializationInfo and StreamingContext classes.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected Uri (System.Runtime.Serialization.SerializationInfo
serializationInfo, System.Runtime.Serialization.StreamingContext
streamingContext);
```

Parameters

`serializationInfo` SerializationInfo

An instance of the SerializationInfo class containing the information required to serialize the new Uri instance.

`streamingContext` StreamingContext

An instance of the StreamingContext class containing the source of the serialized stream associated with the new Uri instance.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

The `serializationInfo` parameter contains a `null` URI.

UriFormatException

The `serializationInfo` parameter contains a URI that is empty.

-or-

The scheme specified is not correctly formed. See CheckSchemeName(String).

-or-

The URI contains too many slashes.

-or-

The password specified in the URI is not valid.

-or-

The host name specified in URI is not valid.

-or-

The file name specified in the URI is not valid.

-or-

The user name specified in the URI is not valid.

-or-

The host or authority name specified in the URI cannot be terminated by backslashes.

-or-

The port number specified in the URI is not valid or cannot be parsed.

-or-

The length of URI exceeds 65519 characters.

-or-

The length of the scheme specified in the URI exceeds 1023 characters.

-or-

There is an invalid character sequence in the URI.

-or-

The MS-DOS path specified in the URI must start with c:\\.

Remarks

This constructor implements the ISerializable interface for the Uri class.

.NET Standard	2.0, 2.1

Uri(String, Boolean)

⊗ **Caution**

This constructor has been deprecated; the dontEscape parameter is always false. Use Uri(string) instead.

Initializes a new instance of the Uri class with the specified URI, with explicit control of character escaping.

C#

```
[System.Obsolete("This constructor has been deprecated; the dontEscape parameter is always false. Use Uri(string) instead.")]
public Uri (string uriString, bool dontEscape);
```

Parameters

`uriString` String

A string that identifies the resource to be represented by the Uri instance. Note that an IPv6 address in string form must be enclosed within brackets. For example, "http://[2607:f8b0:400d:c06::69]".

`dontEscape` Boolean

`true` if `uriString` is completely escaped; otherwise, `false`.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`uriString` is `null`.

UriFormatException

`uriString` is empty or contains only spaces.

-or-

The scheme specified in `uriString` is not valid.

-or-

`uriString` contains too many slashes.

-or-

The password specified in `uriString` is not valid.

-or-

The host name specified in `uriString` is not valid.

-or-

The file name specified in `uriString` is not valid.

-or-

The user name specified in `uriString` is not valid.

-or-

The host or authority name specified in `uriString` cannot be terminated by backslashes.

-or-

The port number specified in `uriString` is not valid or cannot be parsed.

-or-

The length of `uriString` exceeds 65519 characters.

-or-

The length of the scheme specified in `uriString` exceeds 1023 characters.

-or-

There is an invalid character sequence in `uriString`.

-or-

The MS-DOS path specified in `uriString` must start with c:\\.

Examples

The following example creates a Uri instance for the URI `http://www.contoso.com/Hello%20World.htm`. Because the contained URI is completely escaped and is in canonical form, the `dontEscape` parameter can be set to `true`.

```
C#
```

```
Uri myUri = new Uri("http://www.contoso.com/Hello%20World.htm", true);
```

Remarks

This constructor creates a Uri instance from a URI string. It parses the URI and puts it in canonical format.

The `dontEscape` parameter controls whether reserved characters are translated into escape sequences. This parameter should be set to `true` only if you are certain that all reserved characters in the URI have been escaped. Setting the value to `true` for a URI that has not been completely escaped can cause unexpected behavior. It is strongly recommended that you always set this parameter to `false`.

If `dontEscape` is set to `false`, the constructor escapes any reserved characters by checking that all occurrences of percent (%) are followed by a valid escape sequence. If the character sequence following a percent is not valid, the percent is replaced by %25.

This constructor does not ensure that the Uri refers to an accessible resource.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

Uri(String, UriCreationOptions)

Initializes a new instance of the Uri class with the specified URI and additional UriCreationOptions.

```
C#
```

```
public Uri (string uriString, in UriCreationOptions creationOptions);
```

Parameters

`uriString` String

A string that identifies the resource to be represented by the Uri instance.

`creationOptions` UriCreationOptions

Options that control how the Uri is created and behaves.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

Uri(String, UriKind)

Initializes a new instance of the Uri class with the specified URI. This constructor allows you to specify if the URI string is a relative URI, absolute URI, or is indeterminate.

C#

```
public Uri (string uriString, UriKind uriKind);
```

Parameters

`uriString` String

A string that identifies the resource to be represented by the Uri instance. Note that an IPv6 address in string form must be enclosed within brackets. For example, "http://[2607:f8b0:400d:c06::69]".

`uriKind` UriKind

Specifies whether the URI string is a relative URI, absolute URI, or is indeterminate.

Exceptions

ArgumentException

`uriKind` is invalid.

ArgumentNullException

`uriString` is `null`.

UriFormatException

Note: In the .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

`uriString` contains a relative URI and `uriKind` is Absolute.

or

`uriString` contains an absolute URI and `uriKind` is Relative.

or

`uriString` is empty.

-or-

The scheme specified in `uriString` is not correctly formed. See CheckSchemeName(String).

-or-

`uriString` contains too many slashes.

-or-

The password specified in `uriString` is not valid.

-or-

The host name specified in `uriString` is not valid.

-or-

The file name specified in `uriString` is not valid.

-or-

The user name specified in `uriString` is not valid.

-or-

The host or authority name specified in `uriString` cannot be terminated by backslashes.

-or-

The port number specified in `uriString` is not valid or cannot be parsed.

-or-

The length of `uriString` exceeds 65519 characters.

-or-

The length of the scheme specified in `uriString` exceeds 1023 characters.

-or-

There is an invalid character sequence in `uriString`.

-or-

The MS-DOS path specified in `uriString` must start with c:\\.

Remarks

Relative and absolute URIs have different restrictions on their format. For example, a relative URI does not require a scheme or an authority. The value you specify in `uriKind` must match the type of URI passed in `uriString`. However, if RelativeOrAbsolute is specified, the URI string can be relative or absolute.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri(Uri, String)

Initializes a new instance of the Uri class based on the specified base URI and relative URI string.

```
C#

public Uri (Uri baseUri, string? relativeUri);
```

Parameters

`baseUri` Uri

The base URI.

`relativeUri` String

The relative URI to add to the base URI.

Exceptions

ArgumentNullException

`baseUri` is `null`.

ArgumentOutOfRangeException

`baseUri` is not an absolute Uri instance.

UriFormatException

Note: In the .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

The URI formed by combining `baseUri` and `relativeUri` is empty or contains only spaces.

-or-

The scheme specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The URI formed by combining `baseUri` and `relativeUri` contains too many slashes.

-or-

The password specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The host name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The file name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The user name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The host or authority name specified in the URI formed by combining `baseUri` and `relativeUri` cannot be terminated by backslashes.

-or-

The port number specified in the URI formed by combining `baseUri` and `relativeUri` is not valid or cannot be parsed.

-or-

The length of the URI formed by combining `baseUri` and `relativeUri` exceeds 65519 characters.

-or-

The length of the scheme specified in the URI formed by combining `baseUri` and `relativeUri` exceeds 1023 characters.

-or-

There is an invalid character sequence in the URI formed by combining `baseUri` and `relativeUri`.

-or-

The MS-DOS path specified in `uriString` must start with c:\\.

Examples

The following example creates a new instance of the Uri class by combining the relative URIs `http://www.contoso.com` and `catalog/shownew.htm` to form the absolute URI `http://www.contoso.com/catalog/shownew.htm`.

```
C#

Uri baseUri = new Uri("http://www.contoso.com");
 Uri myUri = new Uri(baseUri, "catalog/shownew.htm");

Console.WriteLine(myUri.ToString());
```

Remarks

This constructor creates a Uri instance by combining the `baseUri` and the `relativeUri`. If `relativeUri` is an absolute URI (containing a scheme, host name, and optionally a port number), the Uri instance is created using only `relativeUri`.

If the `baseUri` has relative parts (like `/api`), then the relative part must be terminated with a slash, (like `/api/`), if the relative part of `baseUri` is to be preserved in the constructed Uri.

Additionally, if the `relativeUri` begins with a slash, then it will replace any relative part of the `baseUri`

This constructor does not ensure that the Uri refers to an accessible resource.

Uri(Uri, Uri)

Initializes a new instance of the Uri class based on the combination of a specified base Uri instance and a relative Uri instance.

```
C#

public Uri (Uri baseUri, Uri relativeUri);
```

Parameters

`baseUri` Uri

An absolute Uri that is the base for the new Uri instance.

`relativeUri` Uri

A relative Uri instance that is combined with `baseUri`.

Exceptions

ArgumentException

`baseUri` is not an absolute Uri instance.

ArgumentNullException

`baseUri` is `null`.

ArgumentOutOfRangeException

`baseUri` is not an absolute Uri instance.

UriFormatException

Note: In the .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

The URI formed by combining `baseUri` and `relativeUri` is empty or contains only spaces.

-or-

The scheme specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The URI formed by combining `baseUri` and `relativeUri` contains too many slashes.

-or-

The password specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The host name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The file name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The user name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The host or authority name specified in the URI formed by combining `baseUri` and `relativeUri` cannot be terminated by backslashes.

-or-

The port number specified in the URI formed by combining `baseUri` and `relativeUri` is not valid or cannot be parsed.

-or-

The length of the URI formed by combining `baseUri` and `relativeUri` exceeds 65519 characters.

-or-

The length of the scheme specified in the URI formed by combining `baseUri` and `relativeUri` exceeds 1023 characters.

-or-

There is an invalid character sequence in the URI formed by combining `baseUri` and `relativeUri`.

-or-

The MS-DOS path specified in `uriString` must start with c:\\.

Examples

This example creates an absolute Uri instance, `absoluteUri`, and a relative Uri instance, `relativeUri`. A new Uri instance, `combinedUri`, is then created from these two instances.

C#

```
// Create an absolute Uri from a string.
Uri absoluteUri = new Uri("http://www.contoso.com/");

// Create a relative Uri from a string.  allowRelative = true to allow
for
// creating a relative Uri.
Uri relativeUri = new Uri("/catalog/shownew.htm?date=today",
UriKind.Relative);

// Check whether the new Uri is absolute or relative.
if (!relativeUri.IsAbsoluteUri)
    Console.WriteLine("{0} is a relative Uri.", relativeUri);

// Create a new Uri from an absolute Uri and a relative Uri.
Uri combinedUri = new Uri(absoluteUri, relativeUri);
Console.WriteLine(combinedUri.AbsoluteUri);
```

Remarks

This constructor creates a new Uri instance by combining an absolute Uri instance, `baseUri`, with a relative Uri instance, `relativeUri`. If `relativeUri` is an absolute Uri instance (containing a scheme, host name, and optionally a port number), the Uri instance is created using only `relativeUri`.

If the `baseUri` has relative parts (like `/api`), then the relative part must be terminated with a slash, (like `/api/`), if the relative part of `baseUri` is to be preserved in the constructed Uri.

Additionally, if the `relativeUri` begins with a slash, then it will replace any relative part of the `baseUri`

This constructor does not ensure that the Uri refers to an accessible resource.

UWP	10.0

Uri(Uri, String, Boolean)

> ⊗ **Caution**
>
> This constructor has been deprecated; the dontEscape parameter is always false. Use Uri(Uri, string) instead.

Initializes a new instance of the Uri class based on the specified base and relative URIs, with explicit control of character escaping.

C#

```
[System.Obsolete("This constructor has been deprecated; the dontEscape parameter is always false. Use Uri(Uri, string) instead.")]
public Uri (Uri baseUri, string? relativeUri, bool dontEscape);
```

Parameters

`baseUri` Uri

The base URI.

`relativeUri` String

The relative URI to add to the base URI.

`dontEscape` Boolean

`true` if `uriString` is completely escaped; otherwise, `false`.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`baseUri` is `null`.

ArgumentOutOfRangeException

`baseUri` is not an absolute Uri instance.

UriFormatException

The URI formed by combining `baseUri` and `relativeUri` is empty or contains only spaces.

-or-

The scheme specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The URI formed by combining `baseUri` and `relativeUri` contains too many slashes.

-or-

The password specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The host name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The file name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The user name specified in the URI formed by combining `baseUri` and `relativeUri` is not valid.

-or-

The host or authority name specified in the URI formed by combining `baseUri` and `relativeUri` cannot be terminated by backslashes.

-or-

The port number specified in the URI formed by combining `baseUri` and `relativeUri` is not valid or cannot be parsed.

-or-

The length of the URI formed by combining `baseUri` and `relativeUri` exceeds 65519 characters.

-or-

The length of the scheme specified in the URI formed by combining `baseUri` and `relativeUri` exceeds 1023 characters.

-or-

There is an invalid character sequence in the URI formed by combining `baseUri` and `relativeUri`.

-or-

The MS-DOS path specified in `uriString` must start with c:\\.

Examples

The following example creates a new instance of the Uri class by combining the relative URIs `http://www.contoso.com` and `Hello%20World.htm` to form an absolute URI.

```
C#

Uri baseUri = new Uri("http://www.contoso.com");
Uri myUri = new Uri(baseUri, "Hello%20World.htm",false);
```

Remarks

This constructor creates a Uri instance by combining `baseUri` and `relativeUri`. If the URI passed in `relativeUri` is an absolute URI (containing a scheme, host name, and

optionally a port number), the Uri instance is created using only `relativeUri`.

The `dontEscape` parameter controls whether reserved characters are translated into escape sequences. This parameter should be set to `true` only if you are certain that all reserved characters in the URI have been escaped. Setting the value to `true` for a URI that has not been completely escaped can cause unexpected behavior. It is strongly recommended that you always set this parameter to `false`. If `dontEscape` is set to `false`, the constructor escapes any reserved characters by checking that all occurrences of percent (%) are followed by a valid escape sequence. If the character sequence following a percent is not valid, the percent is replaced by %25.

This constructor does not ensure that the Uri refers to an accessible resource.

Notes to Callers

Because of security concerns, your application should not call this constructor with URI strings from untrusted sources and with `dontEscape` set to `true`. Alternately, you can check a URI string for validity by calling the IsWellFormedOriginalString() method prior to calling this constructor.

Uri.SchemeDelimiter Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the characters that separate the communication protocol scheme from the address portion of the URI. This field is read-only.

C#

```
public static readonly string SchemeDelimiter;
```

Field Value

String

Examples

The following example creates a string from UriSchemeHttp, SchemeDelimiter, and an address. A Uri instance is then created from the string.

C#

```
            string address = "www.contoso.com";
            string uriString = String.Format("{0}{1}{2}/",
Uri.UriSchemeHttp, Uri.SchemeDelimiter, address);
 #if OLDMETHOD
            Uri result;
            if (Uri.TryParse(uriString, false, false, out result) == true)
                Console.WriteLine("{0} is a valid Uri", result.ToString());
            else
                Console.WriteLine("Uri not created");
#endif
            Uri result = new Uri(uriString);
            if (result.IsWellFormedOriginalString())
                Console.WriteLine("{0} is a well formed Uri", uriString);
            else
                Console.WriteLine("{0} is not a well formed Uri",
uriString);
```

Uri.UriSchemeFile Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies that the URI is a pointer to a file. This field is read-only.

C#

```
public static readonly string UriSchemeFile;
```

Field Value

String

Examples

The following example creates a Uri instance and determines whether the scheme is UriSchemeFile.

C#

```
Uri address2 =  new Uri("file://server/filename.ext");
if (address2.Scheme == Uri.UriSchemeFile)
    Console.WriteLine("Uri is a file");
```

Remarks

In .NET Framework version 1.1, a "`file:///path`" URI was translated to "`file:/path`". This has been corrected for version 2.0.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

Uri.AbsolutePath Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the absolute path of the URI.

```
C#

public string AbsolutePath { get; }
```

Property Value

String

The absolute path to the resource.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the path `/catalog/shownew.htm` to the console.

```
C#

Uri baseUri = new Uri("http://www.contoso.com/");
Uri myUri = new Uri(baseUri, "catalog/shownew.htm?date=today");

Console.WriteLine(myUri.AbsolutePath);
```

Remarks

The AbsolutePath property contains the path information that the server uses to resolve requests for information. Typically this is the path to the desired information on the

server's file system, although it also can indicate the application or script the server must run to provide the information.

The path information does not include the scheme, host name, or query portion of the URI.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Uri.AbsoluteUri Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the absolute URI.

C#

```
public string AbsoluteUri { get; }
```

Property Value

String

The entire URI.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the complete contents of the Uri instance to the console. In the example shown, `http://www.contoso.com/catalog/shownew.htm?date=today` is written to the console.

C#

```
Uri baseUri= new Uri("http://www.contoso.com");
Uri myUri = new Uri(baseUri,"catalog/shownew.htm?date=today");
Console.WriteLine(myUri.AbsoluteUri);
```

Remarks

The AbsoluteUri property includes the entire URI stored in the Uri instance, including all fragments and query strings.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.Authority Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the Domain Name System (DNS) host name or IP address and the port number for a server.

```
C#

public string Authority { get; }
```

Property Value

String

The authority component of the URI represented by this instance.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the host name (`www.contoso.com`) and port number (8080) of the server to the console.

```
C#

Uri baseUri = new Uri("http://www.contoso.com:8080/");
Uri myUri = new Uri(baseUri,"shownew.htm?date=today");

Console.WriteLine(myUri.Authority);
```

Remarks

The Authority property is typically a server DNS host name or IP address. This property might include the service port number if it differs from the default port for the URI. If the Authority component contains reserved characters, these are escaped in the string value returned by this property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.DnsSafeHost Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a host name that, after being unescaped if necessary, is safe to use for DNS resolution.

```
C#
public string DnsSafeHost { get; }
```

Property Value

String

The host part of the URI in a format suitable for DNS resolution; or the original host string, if it is already suitable for resolution.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance from a string. It illustrates the difference between the value returned from Host, which returns the host name or address specified in the URI, and the value returned from DnsSafeHost, which returns an address that is safe to use in DNS resolution.

```
C#
// Create new Uri using a string address.
Uri address = new
Uri("http://[fe80::200:39ff:fe36:1a2d%254]/temp/example.htm");

// Make the address DNS safe.
```

```
// The following outputs "[fe80::200:39ff:fe36:1a2d]".
Console.WriteLine(address.Host);

// The following outputs "fe80::200:39ff:fe36:1a2d%254".
Console.WriteLine(address.DnsSafeHost);
```

As explained in Remarks, unescape the host name before resolving it. You can use the UnescapeDataString method to unescape the host name, and you can resolve it by calling the GetHostEntry method.

Remarks

For IPv6 addresses, the brackets ([]) are removed and the ScopeId property is set, if one was specified when this instance was constructed.

If you used an escaped string to construct this instance (for example, `"http://[fe80::200:39ff:fe36:1a2d%254]/temp/example.htm"`), then DnsSafeHost returns an escaped string. Unescape any escaped string returned from `DnsSafeHost` before using that string for DNS resolution (see the Example). If you used an invalid unescaped string to construct this instance (for example, "http://[fe80::200:39ff:fe36:1a2d%4]/temp/example.htm"), then DnsSafeHost returns an unescaped string.

The DnsSafeHost property is dependent on configuration settings in .NET Framework apps, as discussed later in this topic. The IdnHost property is provided as the preferred alternative to using DnsSafeHost, because IdnHost is guaranteed to always be DNS safe.

The DnsSafeHost property was extended in .NET Framework v3.5, 3.0 SP1, and 2.0 SP1 to provide International Resource Identifier (IRI) support based on RFC 3987. However, to ensure application compatibility with prior versions, you must specifically enable it in .NET Framework apps. To enable support for IRI, the following two changes are required:

1. Add the following line to the *machine.config* file under the .NET Framework 2.0 directory:

   `\<section name="uri" type="System.Configuration.UriSection, System, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089" />`

2. Specify whether you want Internationalized Domain Name (IDN) parsing applied to the domain name and whether IRI parsing rules should be applied. This can be done in the *machine.config* or in the *app.config* file. For example, add the following:

   ```
   XML
   ```

```xml
<configuration>
  <uri>
    <idn enabled="All" />
    <iriParsing enabled="true" />
  </uri>
</configuration>
```

Enabling IDN converts all Unicode labels in a domain name to their Punycode equivalents. Punycode names contain only ASCII characters and always start with the xn-- prefix. The reason for this is to support existing DNS servers on the Internet, since most DNS servers only support ASCII characters (see RFC 3940).

Enabling IDN only affects the value of the DnsSafeHost property.

There are three possible values for IDN depending on the DNS servers that are used:

- idn enabled = All

  This value will convert any Unicode domain names to their Punycode equivalents (IDN names).

- idn enabled = AllExceptIntranet

  This value will convert all external Unicode domain names to use the Punycode equivalents (IDN names). In this case to handle international names on the local Intranet, the DNS servers that are used for the Intranet should support Unicode names.

- idn enabled = None

  This value will not convert any Unicode domain names to use Punycode. This is the default value, which is consistent with the .NET Framework 2.0 behavior.

Enabling IRI parsing (iriParsing enabled = `true`) normalizes and checks characters according to the IRI rules in RFC 3987. The default value is `false` and normalizes and checks characters according to RFC 2396 and RFC 2732 (for IPv6 literals).

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.Fragment Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the escaped URI fragment, including the leading '#' character if not empty.

C#

```
public string Fragment { get; }
```

Property Value

String

URI fragment information.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and writes the fragment information to the console.

C#

```
// Create Uri
Uri uriAddress = new Uri("http://www.contoso.com/index.htm#search");
Console.WriteLine(uriAddress.Fragment);
Console.WriteLine("Uri {0} the default port ", uriAddress.IsDefaultPort ?
"uses" : "does not use");

Console.WriteLine("The path of this Uri is {0}",
uriAddress.GetLeftPart(UriPartial.Path));
Console.WriteLine("Hash code {0}", uriAddress.GetHashCode());
// The example displays output similar to the following:
//        #search
```

```
//        Uri uses the default port
//        The path of this Uri is http://www.contoso.com/index.htm
//        Hash code -988419291
```

Remarks

The Fragment property gets any text following a fragment marker (#) in the URI, including the fragment marker itself. Given the URI `http://www.contoso.com/index.htm#main`, the Fragment property would return #main.

The Fragment property is not considered in any Equals comparison.

Uri.Host Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the host component of this instance.

```
C#

public string Host { get; }
```

Property Value

String

The host name. This is usually the DNS host name or IP address of the server.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the host name (`www.contoso.com`) of the server to the console.

```
C#

Uri baseUri = new Uri("http://www.contoso.com:8080/");
Uri myUri = new Uri(baseUri, "shownew.htm?date=today");

Console.WriteLine(myUri.Host);
```

Remarks

Unlike the Authority property, this property value does not include the port number.

Applies to

Uri.HostNameType Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the type of the host name specified in the URI.

C#

```
public UriHostNameType HostNameType { get; }
```

Property Value

UriHostNameType

A member of the UriHostNameType enumeration.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and writes the HostNameType to the console.

C#

```
Uri address1 = new Uri("http://www.contoso.com/index.htm#search");
Console.WriteLine("address 1 {0} a valid scheme name",
      Uri.CheckSchemeName(address1.Scheme) ? " has" : " does not have");

if (address1.Scheme == Uri.UriSchemeHttp)
    Console.WriteLine("Uri is HTTP type");

Console.WriteLine(address1.HostNameType);
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.IdnHost Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the RFC 3490 compliant International Domain Name of the host, using Punycode as appropriate. This string, after being unescaped if necessary, is safe to use for DNS resolution.

```
C#

public string IdnHost { get; }
```

Property Value

String

The hostname, formatted with Punycode according to the IDN standard.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Remarks

This property is provided for the use of lower-level networking protocols that require the domain name in Punycode form. If your code does not require that specific format, use Host for the hostname.

The deprecated DnsSafeHost property is dependent on *app.config* settings, which cannot be changed by Windows Store applications. IdnHost is provided as the preferred alternative to using DnsSafeHost, because IdnHost is guaranteed to always be DNS safe, no matter what the current *app.config* settings might be.

If you used an escaped string to construct this instance (for example, `"http://[fe80::200:39ff:fe36:1a2d%254]/temp/example.htm"`), then IdnHost returns an

escaped string. You should unescape any escaped string returned from IdnHost before using that string for DNS resolution. Be aware that if you used an invalid unescaped string to construct this instance (for example, "http://[fe80::200:39ff:fe36:1a2d%4]/temp/example.htm"), then IdnHost returns an unescaped string.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.IsAbsoluteUri Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the Uri instance is absolute.

```
C#
public bool IsAbsoluteUri { get; }
```

Property Value

Boolean

`true` if the Uri instance is absolute; otherwise, `false`.

Remarks

This property is `true` if the string or Uri instance that was passed into the constructor can be parsed as an absolute Uri instance, which contains a scheme, an authority, and a path. Otherwise, the Uri instance is treated as relative and might omit the scheme or other URI components.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.IsDefaultPort Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the port value of the URI is the default for this scheme.

C#

```
public bool IsDefaultPort { get; }
```

Property Value

Boolean

`true` if the value in the Port property is the default port for this scheme; otherwise, `false`.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and checks whether it uses the default port.

C#

```
// Create Uri
Uri uriAddress = new Uri("http://www.contoso.com/index.htm#search");
Console.WriteLine(uriAddress.Fragment);
Console.WriteLine("Uri {0} the default port ", uriAddress.IsDefaultPort ?
"uses" : "does not use");

Console.WriteLine("The path of this Uri is {0}",
uriAddress.GetLeftPart(UriPartial.Path));
```

```
Console.WriteLine("Hash code {0}", uriAddress.GetHashCode());
// The example displays output similar to the following:
//        #search
//        Uri uses the default port
//        The path of this Uri is http://www.contoso.com/index.htm
//        Hash code -988419291
```

Applies to

Product	Versions

Uri.IsFile Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the specified Uri is a file URI.

C#

```
public bool IsFile { get; }
```

Property Value

Boolean

`true` if the Uri is a file URI; otherwise, `false`.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and determines whether it is a file URI.

C#

```
Uri uriAddress2 =  new Uri("file://server/filename.ext");
Console.WriteLine(uriAddress2.LocalPath);
Console.WriteLine("Uri {0} a UNC path", uriAddress2.IsUnc ? "is" : "is
not");
Console.WriteLine("Uri {0} a local host", uriAddress2.IsLoopback ? "is" :
"is not");
Console.WriteLine("Uri {0} a file", uriAddress2.IsFile ? "is" : "is not");
// The example displays the following output:
//    \\server\filename.ext
//    Uri is a UNC path
```

```
//    Uri is not a local host
//    Uri is a file
```

Remarks

The IsFile property is `true` when the Scheme property equals UriSchemeFile.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.IsLoopback Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the specified Uri references the local host.

C#

```
public bool IsLoopback { get; }
```

Property Value

Boolean

`true` if this Uri references the local host; otherwise, `false`.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and determines whether it references a local host.

C#

```
Uri uriAddress2 =  new Uri("file://server/filename.ext");
Console.WriteLine(uriAddress2.LocalPath);
Console.WriteLine("Uri {0} a UNC path", uriAddress2.IsUnc ? "is" : "is
not");
Console.WriteLine("Uri {0} a local host", uriAddress2.IsLoopback ? "is" :
"is not");
Console.WriteLine("Uri {0} a file", uriAddress2.IsFile ? "is" : "is not");
// The example displays the following output:
//    \\server\filename.ext
//    Uri is a UNC path
```

```
//    Uri is not a local host
//    Uri is a file
```

Remarks

IsLoopback returns `true` if the URI specified when this instance was created was 127.0.0.1, loopback, or localhost, or if the URI did not specify host information (for example, file:///c:Dir/file.txt). All other URIs return `false`.

Applies to

Product	Versions

Uri.IsUnc Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the specified Uri is a universal naming convention (UNC) path.

C#

```
public bool IsUnc { get; }
```

Property Value

Boolean

`true` if the Uri is a UNC path; otherwise, `false`.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and determines whether it is a UNC path.

C#

```
Uri uriAddress2 =  new Uri("file://server/filename.ext");
Console.WriteLine(uriAddress2.LocalPath);
Console.WriteLine("Uri {0} a UNC path", uriAddress2.IsUnc ? "is" : "is
not");
Console.WriteLine("Uri {0} a local host", uriAddress2.IsLoopback ? "is" :
"is not");
Console.WriteLine("Uri {0} a file", uriAddress2.IsFile ? "is" : "is not");
// The example displays the following output:
//    \\server\filename.ext
//    Uri is a UNC path
```

```
//    Uri is not a local host
//    Uri is a file
```

Remarks

The IsUnc property is `true` if the specified Uri instance is a UNC path (such as `\\server\folder`, //server, or `file://server/folder`). This property always returns `true` if the URI has the file:// scheme and specifies a host component.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.LocalPath Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a local operating-system representation of a file name.

C#

```
public string LocalPath { get; }
```

Property Value

String

The local operating-system representation of a file name.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and writes the local path to the console.

C#

```
Uri uriAddress2 =  new Uri("file://server/filename.ext");
Console.WriteLine(uriAddress2.LocalPath);
Console.WriteLine("Uri {0} a UNC path", uriAddress2.IsUnc ? "is" : "is
not");
Console.WriteLine("Uri {0} a local host", uriAddress2.IsLoopback ? "is" :
"is not");
Console.WriteLine("Uri {0} a file", uriAddress2.IsFile ? "is" : "is not");
// The example displays the following output:
//    \\server\filename.ext
//    Uri is a UNC path
```

```
//    Uri is not a local host
//    Uri is a file
```

Remarks

The value returned by this property is unescaped. If the path is recognized as a Windows file path, all forward slashes (/) are replaced by backward slashes (\).

For the URI `file://computer/file.ext`, the absolute path is `/file.ext` and the local path is `\\computer\file.ext`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.OriginalString Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the original URI string that was passed to the Uri constructor.

C#

```
public string OriginalString { get; }
```

Property Value

String

The exact URI specified when this instance was constructed; otherwise, Empty.

Examples

The following example creates a new Uri instance from a string. It illustrates the difference between the value returned from OriginalString, which returns the string that was passed to the constructor, and from a call to ToString, which returns the canonical form of the string.

C#

```
// Create a new Uri from a string address.
Uri uriAddress = new
Uri("HTTP://www.ConToso.com:80//thick%20and%20thin.htm");

// Write the new Uri to the console and note the difference in the two
values.
// ToString() gives the canonical version. OriginalString gives the original
// string that was passed to the constructor.

// The following outputs "http://www.contoso.com//thick and thin.htm".
Console.WriteLine(uriAddress.ToString());

// The following outputs
```

```
"HTTP://www.ConToso.com:80//thick%20and%20thin.htm".
Console.WriteLine(uriAddress.OriginalString);
```

Remarks

If the URI specified to the constructor contained leading or trailing spaces, these spaces are preserved.

The value returned by this property differs from ToString and AbsoluteUri. ToString returns the canonically unescaped form of the URI. AbsoluteUri returns the canonically escaped form of the URI.

When International Resource Identifier (IRI) and Internationalized Domain Name (IDN) support are enabled, OriginalString returns the original non normalized string with Punycode host name if one was used to initialize the Uri instance. Punycode names contain only ASCII characters and always start with the xn-- prefix.

For more information on IRI support, see the Remarks section for the Uri class.

When a Uri object is serialized, the OriginalString is not preserved. The serialization process uses the fully escaped and canonicalized AbsoluteUri property when serializing. For a Uri that contains an IPv6 address, the IPv6 address and the scope ID are included in the serialized Uri object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.PathAndQuery Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the AbsolutePath and Query properties separated by a question mark (?).

```
C#

public string PathAndQuery { get; }
```

Property Value

String

The AbsolutePath and Query properties separated by a question mark (?).

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the URI path (`/catalog/shownew.htm`) and query (`?date=today`) information to the console.

```
C#

Uri baseUri = new Uri("http://www.contoso.com/");
Uri myUri = new Uri(baseUri, "catalog/shownew.htm?date=today");

Console.WriteLine(myUri.PathAndQuery);
```

Remarks

The PathAndQuery property contains the absolute path on the server and the query information sent with the request. It is identical to concatenating the AbsolutePath and Query properties.

The PathAndQuery property is escaped according to RFC 2396 by default. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the PathAndQuery property is escaped according to RFC 3986 and RFC 3987.

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.Port Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the port number of this URI.

C#

```
public int Port { get; }
```

Property Value

Int32

The port number for this URI.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the URI port number to the console. In this case, the value is the default port number for HTTP, port 80.

C#

```
Uri baseUri = new Uri("http://www.contoso.com/");
Uri myUri = new Uri(baseUri,"catalog/shownew.htm?date=today");

Console.WriteLine(myUri.Port);
```

Remarks

The port number defines the protocol port used for contacting the server referenced in the URI. If a port is not specified as part of the URI, the Port property returns the default value for the protocol. If there is no default port number, this property returns -1.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.Query Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets any query information included in the specified URI, including the leading '?' character if not empty.

C#

```
public string Query { get; }
```

Property Value

String

Any query information included in the specified URI.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the query `?date=today` to the console.

C#

```
Uri baseUri = new Uri ("http://www.contoso.com/");
Uri myUri = new Uri (baseUri, "catalog/shownew.htm?date=today");

Console.WriteLine (myUri.Query);
```

Remarks

The Query property contains any query information included in the URI. Query information is separated from the path information by a question mark (?) and continues to the end of the URI. The query information returned includes the leading question mark.

The query information is escaped according to RFC 2396 by default. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the query information is escaped according to RFC 3986 and RFC 3987.

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.Scheme Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the scheme name for this URI.

```
C#
public string Scheme { get; }
```

Property Value

String

The scheme for this URI, converted to lowercase.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example writes the scheme name (http) to the console for the `http://www.contoso.com/` URI.

```
C#
Uri baseUri = new Uri("http://www.contoso.com/");
Uri myUri = new Uri(baseUri, "catalog/shownew.htm?date=today");

Console.WriteLine(myUri.Scheme);
```

Remarks

The Scheme property returns the scheme used to initialize the Uri instance. This property does not indicate that the scheme used to initialize the Uri instance was recognized.

The following table shows examples of some possible values returned by the Scheme property.

Expand table

Scheme	Description
file	The resource is a file on the local computer.
ftp	The resource is accessed through FTP.
gopher	The resource is accessed through the Gopher protocol.
http	The resource is accessed through HTTP.
https	The resource is accessed through SSL-encrypted HTTP.
ldap	The resource is accessed through the LDAP protocol.
mailto	The resource is an email address and accessed through the SMTP protocol.
net.pipe	The resource is accessed through a named pipe.
net.tcp	The resource is accessed from TCP endpoint.
news	The resource is accessed through the NNTP protocol.
nntp	The resource is accessed through the NNTP protocol.
telnet	The resource is accessed through the TELNET protocol.
uuid	The resource is accessed through a unique UUID endpoint name for communicating with a service.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.Segments Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an array containing the path segments that make up the specified URI.

```
C#

public string[] Segments { get; }
```

Property Value

String[]

The path segments that make up the specified URI.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance with 3 segments and displays the segments on the screen.

```
C#

Uri uriAddress1 = new Uri("http://www.contoso.com/title/index.htm");
Console.WriteLine("The parts are {0}, {1}, {2}", uriAddress1.Segments[0],
uriAddress1.Segments[1], uriAddress1.Segments[2]);
```

Remarks

The Segments property returns an array of strings containing the "segments" (substrings) that form the URI's absolute path. The first segment is obtained by parsing

the absolute path from its first character until you reach a slash (/) or the end of the path. Each additional segment begins at the first character after the preceding segment, and terminates with the next slash or the end of the path. (A URI's absolute path contains everything after the host and port and before the query and fragment.)

The following example shows the absolute path and segments for two URIs. The second example illustrates that the fragment and query are not part of the absolute path and therefore are not segments.

Absolute URI: `http://www.contoso.com/Chapters/Chapter1/Sections/Section1.htm`

Absolute path: /Chapters/Chapter1/Sections/Section1.htm

Segments:

- /
- Chapters/
- Chapter1/
- Sections/
- Section1.htm

Absolute URI: `http://www.contoso.com/Chapters/Chapter1/Sections/Section1.htm#page1?answer=NO`

Absolute path: /Chapters/Chapter1/Sections/Section1.htm

Segments:

- /
- Chapters/
- Chapter1/
- Sections/
- Section1.htm

Note that because the absolute path starts with a '/', the first segment contains it and nothing else.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.UserEscaped Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a value that indicates whether the URI string was completely escaped before the Uri instance was created.

```
C#

public bool UserEscaped { get; }
```

Property Value

Boolean

`true` if the `dontEscape` parameter was set to `true` when the Uri instance was created; otherwise, `false`.

Examples

The following example creates a Uri instance and determines whether it was fully escaped when it was created.

```
C#

Uri uriAddress = new Uri ("http://user:password@www.contoso.com/index.htm
");
Console.WriteLine(uriAddress.UserInfo);
Console.WriteLine("Fully Escaped {0}", uriAddress.UserEscaped ? "yes" :
"no");
```

Remarks

The UserEscaped property is set to `true` to indicate that the string used to create the Uri instance was completely escaped before it was passed to the constructor; that is, the `dontEscape` parameter of the constructor call was set to `true`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.UserInfo Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the user name, password, or other user-specific information associated with the specified URI.

C#

```
public string UserInfo { get; }
```

Property Value

String

The user information associated with the URI. The returned value does not include the '@' character reserved for delimiting the user information part of the URI.

Exceptions

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates a Uri instance and writes the user information to the console.

C#

```
Uri uriAddress = new Uri ("http://user:password@www.contoso.com/index.htm
");
Console.WriteLine(uriAddress.UserInfo);
Console.WriteLine("Fully Escaped {0}", uriAddress.UserEscaped ? "yes" :
"no");
```

Remarks

The value returned by this property is usually in the format "userName:password".

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.Canonicalize Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.Canonicalize has been deprecated and is not supported.

Converts the internally stored URI to canonical form.

C#

```
[System.Obsolete("Uri.Canonicalize has been deprecated and is not
supported.")]
protected virtual void Canonicalize ();
```

Attributes ObsoleteAttribute

Exceptions

InvalidOperationException

This instance represents a relative URI, and this method is valid only for absolute URIs.

UriFormatException

The URI is incorrectly formed.

Remarks

Stores the canonical version of the URI internally.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

Uri.CheckHostName(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified host name is a valid DNS name.

```
C#

public static UriHostNameType CheckHostName (string? name);
```

Parameters

name String

The host name to validate. This can be an IPv4 or IPv6 address or an Internet host name.

Returns

UriHostNameType

The type of the host name. If the type of the host name cannot be determined or if the host name is `null` or a zero-length string, this method returns Unknown.

Examples

The following example checks whether the host name is valid.

```
C#

Console.WriteLine(Uri.CheckHostName("www.contoso.com"));
```

Remarks

The CheckHostName method checks that the host name provided meets the requirements for a valid Internet host name. It does not, however, perform a host-name lookup to verify the existence of the host.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.CheckSchemeName(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the specified scheme name is valid.

C#

```
public static bool CheckSchemeName (string? schemeName);
```

Parameters

schemeName String

The scheme name to validate.

Returns

Boolean

`true` if the scheme name is valid; otherwise, `false`.

Examples

The following example creates a Uri instance and checks whether the scheme name is valid.

C#

```
Uri address1 = new Uri("http://www.contoso.com/index.htm#search");
Console.WriteLine("address 1 {0} a valid scheme name",
      Uri.CheckSchemeName(address1.Scheme) ? " has" : " does not have");

if (address1.Scheme == Uri.UriSchemeHttp)
    Console.WriteLine("Uri is HTTP type");

Console.WriteLine(address1.HostNameType);
```

Remarks

This method checks the scheme name for validity according to RFC 2396 by default. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, this method checks the scheme name for validity according to RFC 3986. The scheme name must begin with a letter and must contain only letters, digits, and the characters ".", "+", or "-".

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions

Uri.CheckSecurity Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> **Caution**
>
> Uri.CheckSecurity has been deprecated and is not supported.

Calling this method has no effect.

C#

```
[System.Obsolete("Uri.CheckSecurity has been deprecated and is not supported.")]
protected virtual void CheckSecurity ();
```

Attributes ObsoleteAttribute

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*

Uri.Compare(Uri, Uri, UriComponents, UriFormat, StringComparison) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the specified parts of two URIs using the specified comparison rules.

C#

```
public static int Compare (Uri? uri1, Uri? uri2, UriComponents
partsToCompare, UriFormat compareFormat, StringComparison comparisonType);
```

Parameters

`uri1` Uri

The first URI.

`uri2` Uri

The second URI.

`partsToCompare` UriComponents

A bitwise combination of the UriComponents values that specifies the parts of `uri1` and `uri2` to compare.

`compareFormat` UriFormat

One of the enumeration values that specifies the character escaping used when the URI components are compared.

`comparisonType` StringComparison

One of the enumeration values that specifies the culture, case, and sort rules for the comparison.

Returns

Int32

A value that indicates the lexical relationship between the compared Uri components.

Expand table

Value	Meaning
Less than zero	`uri1` is less than `uri2`.
Zero	`uri1` equals `uri2`.
Greater than zero	`uri1` is greater than `uri2`.

Exceptions

ArgumentException

`comparisonType` is not a valid StringComparison value.

Remarks

If both `uri1` and `uri2` are `null`, this method returns 0. When comparing URI values, a relative URI is always less than an absolute URI, and a non-null URI is always greater than a null URI. For cases where both `uri1` and `uri2` are not `null` and are both relative URIs or both absolute URIs, the String.Compare(String, String, StringComparison) method performs the comparison.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Uri.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares two Uri instances for equality.

C#

```
public override bool Equals (object? comparand);
```

Parameters

comparand Object

The URI or a URI identifier to compare with the current instance.

Returns

Boolean

`true` if the two instances represent the same URI; otherwise, `false`.

Examples

This example creates two Uri instances from strings and compares them to determine whether they represent the same value. `address1` and `address2` are the same because the Fragment portion is ignored for this comparison. The outcome is written to the console.

C#

```
// Create some Uris.
Uri address1 = new Uri("http://www.contoso.com/index.htm#search");
Uri address2 = new Uri("http://www.contoso.com/index.htm");
if (address1.Equals(address2))
    Console.WriteLine("The two addresses are equal");
else
```

```
    Console.WriteLine("The two addresses are not equal");
// Will output "The two addresses are equal"
```

Remarks

The Equals method compares the two instances without regard to user information (UserInfo) and fragment (Fragment) parts that they might contain. For example, given the URIs `http://www.contoso.com/index.htm#search` and `http://user:password@www.contoso.com/index.htm`, the Equals method would return `true`.

If one Uri instance is formed with a Unicode host name and `comparand` parameter contains a Uri instance or identifier that is formed with a host name that has the equivalent Punycode host name, then Equals returns `true` only if International Resource Identifier (IRI) and Internationalized Domain Name (IDN) support are enabled. Punycode names contain only ASCII characters and always start with the xn-- prefix.

For more information on IRI support, see the Remarks section for the Uri class.

> **Note**
>
> In the .NET Framework versions 1.0 and 1.1, the **Query** is also ignored.

> **Note**
>
> The **Equals** method can be overridden in a derived class; use caution as a malicious entity could modify the method. You should not use this method to perform security checks unless you know that this instance came from a trusted source.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.Escape Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.Escape has been deprecated and is not supported.

Converts any unsafe or reserved characters in the path component to their hexadecimal character representations.

C#

```
[System.Obsolete("Uri.Escape has been deprecated and is not supported.")]
protected virtual void Escape ();
```

Attributes ObsoleteAttribute

Exceptions

UriFormatException

The URI passed from the constructor is invalid. This exception can occur if a URI has too many characters or the URI is relative.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

Uri.EscapeDataString(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a string to its escaped representation.

```
C#
public static string EscapeDataString (string stringToEscape);
```

Parameters

`stringToEscape` String

The string to escape.

Returns

String

The escaped representation of `stringToEscape`.

Exceptions

ArgumentNullException

`stringToEscape` is `null`.

UriFormatException

Note: In the .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

The length of `stringToEscape` exceeds 32766 characters.

Remarks

By default, the EscapeDataString method converts all characters except for RFC 2396 unreserved characters to their hexadecimal representation. If International Resource

Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the EscapeDataString method converts all characters, except for RFC 3986 unreserved characters, to their hexadecimal representation. All Unicode characters are converted to UTF-8 format before being escaped.

This method assumes that `stringToEscape` has no escape sequences in it.

By default, the string is escaped according to RFC 2396. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the string is escaped according to RFC 3986 and RFC 3987. See these RFCs for a definition of reserved and unreserved characters.

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.EscapeString(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.EscapeString has been deprecated. Use GetComponents() or Uri.EscapeDataString to escape a Uri component or a string.

Converts a string to its escaped representation.

C#

```
[System.Obsolete("Uri.EscapeString has been deprecated. Use GetComponents()
or Uri.EscapeDataString to escape a Uri component or a string.")]
protected static string EscapeString (string? str);
```

Parameters

`str` String

The string to transform to its escaped representation.

Returns

String

The escaped representation of the string.

Attributes ObsoleteAttribute

Remarks

The EscapeString method converts RFC 2396 reserved characters and all characters with a character value greater than 127 to hexadecimal representation. All Unicode characters are converted to UTF-8 format before being escaped.

By default, the string is escaped according to RFC 2396. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the string is escaped according to RFC 3986 and RFC 3987.

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

Uri.EscapeUriString(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.EscapeUriString can corrupt the Uri string in some cases. Consider using Uri.EscapeDataString for query string components instead.

Converts a URI string to its escaped representation.

C#

```
[System.Obsolete("Uri.EscapeUriString can corrupt the Uri string in some cases. Consider using Uri.EscapeDataString for query string components instead.", DiagnosticId="SYSLIB0013", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public static string EscapeUriString (string stringToEscape);
```

Parameters

`stringToEscape` String

The string to escape.

Returns

String

The escaped representation of `stringToEscape`.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`stringToEscape` is `null`.

UriFormatException

The length of `stringToEscape` exceeds 32766 characters.

```
    Note: In <a href="https://docs.microsoft.com/previous-
versions/br230232(v=vs.110)">.NET for Windows Store apps</a> or the <a
href="https://docs.microsoft.com/dotnet/standard/cross-platform/cross-
platform-development-with-the-portable-class-library">Portable Class
Library</a>, catch the base class exception, <xref data-throw-if-not-
resolved="true" uid="System.FormatException"></xref>, instead.
```

Remarks

Use the EscapeUriString method to prepare an unescaped URI string to be a parameter to the Uri constructor.

By default, the EscapeUriString method converts all characters, except RFC 2396 unreserved characters, to their hexadecimal representation. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the EscapeUriString method converts all characters, except for RFC 3986 unreserved characters, to their hexadecimal representation. All Unicode characters are converted to UTF-8 format before being escaped.

This method assumes that `stringToEscape` has no escape sequences in it.

By default, the string is escaped according to RFC 2396. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the string is escaped according to RFC 3986 and RFC 3987. See these RFCs for a definition of reserved and unreserved characters.

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5 *(6, 7, 8, 9)*
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.FromHex(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the decimal value of a hexadecimal digit.

C#

```
public static int FromHex (char digit);
```

Parameters

`digit` Char

The hexadecimal digit (0-9, a-f, A-F) to convert.

Returns

Int32

A number from 0 to 15 that corresponds to the specified hexadecimal digit.

Exceptions

ArgumentException

`digit` is not a valid hexadecimal digit (0-9, a-f, A-F).

Examples

The following example determines whether a character is a hexadecimal character and, if it is, writes the corresponding decimal value to the console.

C#

```
char  testChar = 'e';
if (Uri.IsHexDigit(testChar) == true)
    Console.WriteLine("'{0}' is the hexadecimal representation of {1}",
testChar, Uri.FromHex(testChar));
```

```
else
    Console.WriteLine("'{0}' is not a hexadecimal character", testChar);

string returnString = Uri.HexEscape(testChar);
Console.WriteLine("The hexadecimal value of '{0}' is {1}", testChar,
returnString);
```

Remarks

The FromHex method converts a character representing a hexadecimal digit (0-9, a-f, A-F) to its decimal value (0 to 15). If `digit` is not a valid hexadecimal digit, an ArgumentException exception is thrown.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Uri.GetComponents(UriComponents, UriFormat) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the specified components of the current instance using the specified escaping for special characters.

C#

```
public string GetComponents (UriComponents components, UriFormat format);
```

Parameters

`components` UriComponents

A bitwise combination of the UriComponents values that specifies which parts of the current instance to return to the caller.

`format` UriFormat

One of the enumeration values that controls how special characters are escaped.

Returns

String

The components of the current instance.

Exceptions

ArgumentOutOfRangeException

`components` is not a combination of valid UriComponents values.

InvalidOperationException

The current Uri is not an absolute URI. Relative URIs cannot be used with this method.

Remarks

The Query, Fragment, Scheme, UserInfo, Host, Port, and Path components do not include the delimiter. You can combine the KeepDelimiter flag (using the bitwise OR operator) with any of those values to get the value with the delimiter. For all other UriComponents values, and combinations of values, the delimiters are included in the returned value.

The components are returned in the order that they appear in the URI. For example, if Scheme is specified, it appears first.

When International Resource Identifier (IRI) and Internationalized Domain Name (IDN) support are enabled, the number of characters returned in the String increases. Punycode names used to support IRI contain only ASCII characters and always start with the xn-- prefix. When IRI and IDN are enabled, Unicode surrogate characters are handled correctly by the GetComponents method.

For more information on IRI support, see the Remarks section for the Uri class.

> **Note**
>
> If the **GetComponents** method is called with `format` set to **Unescaped** , you cannot use the return value as an argument to a **Uri** constructor to create an equivalent **Uri**.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the hash code for the URI.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash value generated for this URI.

Examples

The following example creates a Uri instance and writes the hash code to the console.

C#

```
// Create Uri
Uri uriAddress = new Uri("http://www.contoso.com/index.htm#search");
Console.WriteLine(uriAddress.Fragment);
Console.WriteLine("Uri {0} the default port ", uriAddress.IsDefaultPort ?
"uses" : "does not use");

Console.WriteLine("The path of this Uri is {0}",
uriAddress.GetLeftPart(UriPartial.Path));
Console.WriteLine("Hash code {0}", uriAddress.GetHashCode());
// The example displays output similar to the following:
//        #search
//        Uri uses the default port
//        The path of this Uri is http://www.contoso.com/index.htm
//        Hash code -988419291
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.GetLeftPart(UriPartial) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the specified portion of a Uri instance.

C#

```
public string GetLeftPart (UriPartial part);
```

Parameters

`part` UriPartial

One of the enumeration values that specifies the end of the URI portion to return.

Returns

String

The specified portion of the Uri instance.

Exceptions

InvalidOperationException

The current Uri instance is not an absolute instance.

ArgumentException

The specified `part` is not valid.

Examples

The following example creates a Uri instance and writes the path to the console.

C#

```
// Create Uri
Uri uriAddress = new Uri("http://www.contoso.com/index.htm#search");
Console.WriteLine(uriAddress.Fragment);
Console.WriteLine("Uri {0} the default port ", uriAddress.IsDefaultPort ? "uses" : "does not use");

Console.WriteLine("The path of this Uri is {0}", uriAddress.GetLeftPart(UriPartial.Path));
Console.WriteLine("Hash code {0}", uriAddress.GetHashCode());
// The example displays output similar to the following:
//        #search
//        Uri uses the default port
//        The path of this Uri is http://www.contoso.com/index.htm
//        Hash code -988419291
```

Remarks

The GetLeftPart method returns a string containing the leftmost portion of the URI string, ending with the portion specified by `part`.

GetLeftPart includes delimiters in the following cases:

- Scheme includes the scheme delimiter.
- Authority does not include the path delimiter.
- Path includes the path delimiter and any delimiters in the original URI up to the query or fragment delimiter.
- Query includes the Path, plus the query and its delimiter.

The following examples show a URI and the results of calling GetLeftPart with Scheme, Authority, Path, or Query.

Expand table

Uri.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the data needed to serialize the current instance.

C#

```
protected void GetObjectData (System.Runtime.Serialization.SerializationInfo
serializationInfo, System.Runtime.Serialization.StreamingContext
streamingContext);
```

Parameters

`serializationInfo` SerializationInfo

The information required to serialize the Uri.

`streamingContext` StreamingContext

An object that contains the source and destination of the serialized stream associated with the Uri.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.HexEscape(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified character into its hexadecimal equivalent.

C#

```
public static string HexEscape (char character);
```

Parameters

`character` Char

The character to convert to hexadecimal representation.

Returns

String

The hexadecimal representation of the specified character.

Exceptions

ArgumentOutOfRangeException

`character` is greater than 255.

Examples

The following example converts a character to its hexadecimal equivalent and writes it to the console.

C#

```
char  testChar = 'e';
if (Uri.IsHexDigit(testChar) == true)
    Console.WriteLine("'{0}' is the hexadecimal representation of {1}",
testChar, Uri.FromHex(testChar));
```

```
else
    Console.WriteLine("'{0}' is not a hexadecimal character", testChar);

string returnString = Uri.HexEscape(testChar);
Console.WriteLine("The hexadecimal value of '{0}' is {1}", testChar,
returnString);
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.HexUnescape(String, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a specified hexadecimal representation of a character to the character.

```
C#
public static char HexUnescape (string pattern, ref int index);
```

Parameters

pattern String

The hexadecimal representation of a character.

index Int32

The location in `pattern` where the hexadecimal representation of a character begins.

Returns

Char

The character represented by the hexadecimal encoding at position `index`. If the character at `index` is not hexadecimal encoded, the character at `index` is returned. The value of `index` is incremented to point to the character following the one returned.

Exceptions

ArgumentOutOfRangeException

`index` is less than 0 or greater than or equal to the number of characters in `pattern`.

Remarks

The following code example determines whether a character is hexadecimal encoded and, if so, writes the equivalent character to the console.

C#

```
string testString = "%75";
int index = 0;
if (Uri.IsHexEncoding(testString, index))
     Console.WriteLine("The character is {0}", Uri.HexUnescape(testString,
ref index));
else
     Console.WriteLine("The character is not hexadecimal encoded");
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.IsBadFileSystemCharacter(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.IsBadFileSystemCharacter has been deprecated and is not supported.

Indicates whether a character is invalid in a file system name.

C#

```
[System.Obsolete("Uri.IsBadFileSystemCharacter has been deprecated and is not supported.")]
protected virtual bool IsBadFileSystemCharacter (char character);
```

Parameters

`character` Char

The Char to test.

Returns

Boolean

`true` if the specified character is invalid; otherwise, `false`.

Attributes ObsoleteAttribute

Remarks

The character is analyzed according to the rules for the NTFS file system.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*

Uri.IsBaseOf(Uri) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the current Uri instance is a base of the specified Uri instance.

```
C#

public bool IsBaseOf (Uri uri);
```

Parameters

uri Uri

The specified URI to test.

Returns

Boolean

`true` if the current Uri instance is a base of `uri`; otherwise, `false`.

Exceptions

ArgumentNullException

`uri` is `null`.

Examples

This example creates a Uri instance that represents a base Uri instance. It then creates a second Uri instance from a string. It calls IsBaseOf to determine whether the base instance is the base of the second instance. The outcome is written to the console.

```
C#

// Create a base Uri.
Uri baseUri = new Uri("http://www.contoso.com/");
```

```
// Create a new Uri from a string.
Uri uriAddress = new Uri("http://www.contoso.com/index.htm?date=today");

// Determine whether BaseUri is a base of UriAddress.
if (baseUri.IsBaseOf(uriAddress))
    Console.WriteLine("{0} is the base of {1}", baseUri, uriAddress);
```

Remarks

IsBaseOf is used to compare the current Uri instance to a specified Uri to determine whether this URI is a base for the specified Uri. When comparing two Uri objects to determine a base relationship, the user information (UserInfo) is not evaluated. When comparing two URIs (uri1 and uri2), uri1 is the base of uri2 if, when you ignore everything in uri1 and uri2 after the last slash (/), uri2 starts with exactly uri1. Using http://host/path/path/file?query as the base URI, the following table shows whether it is a base for other URIs.

Expand table

URI	http://host/path/path/file?query is base of
http://host/path/path/file/	yes
http://host/path/path/#fragment	yes
http://host/path/path/MoreDir/"	yes
http://host/path/path/OtherFile?Query	yes
http://host/path/path/	yes
http://host/path/path/file	yes
http://host/path/path	no
http://host/path/path?query	no
http://host/path/path#Fragment	no
http://host/path/path2/	no
://host/path/path2/MoreDir	no
http://host/path/File	no

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.IsExcludedCharacter(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.IsExcludedCharacter has been deprecated and is not supported.

Determines whether the specified character should be escaped.

C#

```
[System.Obsolete("Uri.IsExcludedCharacter has been deprecated and is not supported.")]
protected static bool IsExcludedCharacter (char character);
```

Parameters

`character` Char

The character to test.

Returns

Boolean

`true` if the specified character should be escaped; otherwise, `false`.

Attributes ObsoleteAttribute

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*

Product	Versions *(Obsolete)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*

Uri.IsHexDigit(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether a specified character is a valid hexadecimal digit.

C#

```
public static bool IsHexDigit (char character);
```

Parameters

`character` Char

The character to validate.

Returns

Boolean

`true` if the character is a valid hexadecimal digit; otherwise, `false`.

Examples

The following example determines whether a character is a hexadecimal character and, if it is, writes the corresponding decimal value to the console.

C#

```
char  testChar = 'e';
if (Uri.IsHexDigit(testChar) == true)
    Console.WriteLine("'{0}' is the hexadecimal representation of {1}",
testChar, Uri.FromHex(testChar));
else
    Console.WriteLine("'{0}' is not a hexadecimal character", testChar);

string returnString = Uri.HexEscape(testChar);
Console.WriteLine("The hexadecimal value of '{0}' is {1}", testChar,
returnString);
```

Remarks

Hexadecimal digits are the digits 0 to 9 and the letters A-F or a-f.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Uri.IsHexEncoding(String, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether a character in a string is hexadecimal encoded.

```
C#
public static bool IsHexEncoding (string pattern, int index);
```

Parameters

pattern String

The string to check.

index Int32

The location in `pattern` to check for hexadecimal encoding.

Returns

Boolean

`true` if `pattern` is hexadecimal encoded at the specified location; otherwise, `false`.

Examples

The following code example determines whether a character is hexadecimal encoded and, if so, writes the equivalent character to the console.

```
C#
string testString = "%75";
int index = 0;
if (Uri.IsHexEncoding(testString, index))
     Console.WriteLine("The character is {0}", Uri.HexUnescape(testString,
ref index));
```

```
else
    Console.WriteLine("The character is not hexadecimal encoded");
```

Remarks

The IsHexEncoding method checks for hexadecimal encoding that follows the pattern "%hexhex" in a string, where "hex" is a digit from 0 to 9 or a letter from A-F (case-insensitive).

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.IsReservedCharacter(Char) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.IsReservedCharacter has been deprecated and is not supported.

Determines whether the specified character is a reserved character.

C#

```
[System.Obsolete("Uri.IsReservedCharacter has been deprecated and is not supported.")]
protected virtual bool IsReservedCharacter (char character);
```

Parameters

`character` Char

The character to test.

Returns

Boolean

`true` if the specified character is a reserved character otherwise, `false`.

Attributes ObsoleteAttribute

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*

Product	Versions *(Obsolete)*

Uri.IsWellFormedOriginalString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the string used to construct this Uri was well-formed and does not require further escaping.

```
C#
public bool IsWellFormedOriginalString ();
```

Returns

Boolean

`true` if the string was well-formed; otherwise, `false`.

Remarks

The string is considered to be well-formed in accordance with RFC 2396 and RFC 2732 by default. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing is enabled, the string is considered to be well-formed in accordance with RFC 3986 and RFC 3987

The string is considered poorly formed, causing the method to return false, if any of the following conditions occur.

Expand table

Error	Example
The string is not correctly escaped.	`http://www.contoso.com/path???/file name`
The string is an absolute Uri that represents an implicit file Uri.	`c:\\directory\filename`
The string is an absolute URI that is missing a slash before the path.	`file://c:/directory/filename`

Error	Example
The string contains unescaped backslashes even if they are treated as forward slashes.	`http:\\host/path/file`
The string represents a hierarchical absolute Uri and does not contain "://".	`www.contoso.com/path/file`
The parser for the Uri.Scheme indicates that the original string was not well-formed.	The example depends on the scheme of the URI.

By default, the string used to construct this Uri are considered well-formed in accordance with RFC 2396 and RFC 2732.

When International Resource Identifier (IRI) and Internationalized Domain Name (IDN) support are enabled, the string used to construct this Uri are considered well-formed in accordance with RFC 3986 and RFC 3987. Punycode names used to support IRI contain only ASCII characters and always start with the xn-- prefix.

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.IsWellFormedUriString(String, UriKind) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the string is well-formed by attempting to construct a URI with the string and ensures that the string does not require further escaping.

C#

```
public static bool IsWellFormedUriString (string? uriString, UriKind
uriKind);
```

Parameters

`uriString` String

The string used to attempt to construct a Uri.

`uriKind` UriKind

The type of the Uri in `uriString`.

Returns

Boolean

`true` if the string was well-formed; otherwise, `false`.

Remarks

In versions of .NET before version 4.5, by default the string is considered well-formed in accordance with RFC 2396 and RFC 2732. If International Resource Identifiers (IRIs) or Internationalized Domain Name (IDN) parsing are enabled, the string is considered well-formed in accordance with RFC 3986 and RFC 3987.

Beginning in .NET 4.5, strings are always considered well-formed in accordance with RFC 3986 and RFC 3987, whether or not IRI or IDN are enabled. Note, however, that this is only true for apps that target .NET 4.5 or later. Apps that target .NET 4.0 invoke compatibility code, and experience the old (pre-4.5) behavior.

The string is considered poorly formed, causing the method to return false, if any of the following conditions occur

Expand table

Error	Example
The string is not correctly escaped.	`http://www.contoso.com/path???/filename`
The string is an absolute Uri that represents an implicit file Uri.	`c:\\directory\filename`
The string is an absolute URI that is missing a slash before the path.	`file://c:/directory/filename`
The string contains unescaped backslashes even if they will be treated as forward slashes	`http:\\\host/path/file`
The string represents a hierarchical absolute Uri and does not contain "://"	`www.contoso.com/path/file`
The parser for the Scheme indicates that the original string was not well-formed.	The example depends on the scheme of the URI.
Beginning with .NET 4.5, relative URIs with a colon (':') in their first segment are not considered well-formed.	`2013.05.29_14:33:41`

For more information on IRI support, see the Remarks section for the Uri class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.MakeRelative(Uri) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.MakeRelative has been deprecated. Use MakeRelativeUri(Uri uri) instead.

Determines the difference between two Uri instances.

C#

```
[System.Obsolete("Uri.MakeRelative has been deprecated. Use MakeRelativeUri(Uri uri)
instead.")]
public string MakeRelative (Uri toUri);
```

Parameters

`toUri` Uri

The URI to compare to the current URI.

Returns

String

If the hostname and scheme of this URI instance and `toUri` are the same, then this method returns a String that represents a relative URI that, when appended to the current URI instance, yields the `toUri` parameter.

If the hostname or scheme is different, then this method returns a String that represents the `toUri` parameter.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`toUri` is `null`.

InvalidOperationException

This instance represents a relative URI, and this method is valid only for absolute URIs.

Examples

The following example creates 2 Uri instances. The difference in the path information is written to the console.

C#

```
// Create a base Uri.
Uri address1 = new Uri("http://www.contoso.com/");

// Create a new Uri from a string.
Uri address2 = new Uri("http://www.contoso.com/index.htm?date=today");

// Determine the relative Uri.
Console.WriteLine("The difference is {0}", address1.MakeRelativeUri(address2));
```

Remarks

The following table shows the URI instance, `toUri`, and the results of calling MakeRelative.

Expand table

Current URI instance	`toUri`	Return value
`http://www.contoso.com/`	`http://www.contoso.com/test/test.htm`	`test/test.htm`
`http://www.contoso.com/test1/`	`http://www.contoso.com/`	`../`
`http://www.contoso.com:8000/`	`http://www.contoso.com/test/test.htm`	`http://www.contoso.com/test/test.htm`
`http://username@www.contoso.com/`	`http://www.contoso.com/test1/test1.txt`	`test1/test1.txt`

User information, if present in the URI, is ignored.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*

Uri.MakeRelativeUri(Uri) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines the difference between two Uri instances.

```
C#

public Uri MakeRelativeUri (Uri uri);
```

Parameters

uri Uri

The URI to compare to the current URI.

Returns

Uri

If the hostname and scheme of this URI instance and `uri` are the same, then this method returns a relative Uri that, when appended to the current URI instance, yields `uri`.

If the hostname or scheme is different, then this method returns a Uri that represents the `uri` parameter.

Exceptions

ArgumentNullException

`uri` is `null`.

InvalidOperationException

This instance represents a relative URI, and this property is valid only for absolute URIs.

Examples

The following example creates 2 Uri instances. The difference in the path information is written to the console.

```
C#

// Create a base Uri.
Uri address1 = new Uri("http://www.contoso.com/");
```

```
// Create a new Uri from a string.
Uri address2 = new Uri("http://www.contoso.com/index.htm?date=today");

// Determine the relative Uri.
Console.WriteLine("The difference is {0}", address1.MakeRelativeUri(address2));
```

Remarks

The following table shows the URI instance, `toUri`, and the results of calling MakeRelativeUri.

Expand table

Current URI instance	`toUri`	Return value
`http://www.contoso.com/`	`http://www.contoso.com/test/test.htm`	`test/test.htm`
`http://www.contoso.com/test1/`	`http://www.contoso.com/`	`../`
`http://www.contoso.com:8000/`	`http://www.contoso.com/test/test.htm`	`http://www.contoso.com/test/test.htm`
`http://username@www.contoso.com/`	`http://www.contoso.com/test1/test1.txt`	`test1/test1.txt`

User information, if present in the URI, is ignored.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.Parse has been deprecated and is not supported.

Parses the URI of the current instance to ensure it contains all the parts required for a valid URI.

C#

```
[System.Obsolete("Uri.Parse has been deprecated and is not supported.")]
protected virtual void Parse ();
```

Attributes ObsoleteAttribute

Exceptions

UriFormatException

The Uri passed from the constructor is invalid.

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*
.NET Standard	*(2.0, 2.1)*

Uri.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets a canonical string representation for the specified Uri instance.

C#

```
public override string ToString ();
```

Returns

String

The unescaped canonical representation of the Uri instance. All characters are unescaped except #, ?, and %.

Examples

The following example creates a new Uri instance from a string. It illustrates the difference between the value returned from OriginalString, which returns the string that was passed to the constructor, and from a call to ToString, which returns the canonical form of the string.

C#

```
// Create a new Uri from a string address.
Uri uriAddress = new
Uri("HTTP://www.Contoso.com:80/thick%20and%20thin.htm");

// Write the new Uri to the console and note the difference in the two
values.
// ToString() gives the canonical version.  OriginalString gives the orginal
// string that was passed to the constructor.

// The following outputs "http://www.contoso.com/thick and thin.htm".
Console.WriteLine(uriAddress.ToString());
```

```
// The following outputs "HTTP://www.Contoso.com:80/thick%20and%20thin.htm".
Console.WriteLine(uriAddress.OriginalString);
```

Remarks

The string returned by this method does not contain port information when the port is the default port for the scheme.

> **Note**
>
> The string returned by the **ToString** method may contain control characters, which can corrupt the state of a console application. You can use the **GetComponents** method with the **UriFormat.SafeUnescaped** format to remove control characters from the returned string.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Uri.TryCreate Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new Uri. Does not throw an exception if the Uri cannot be created.

Overloads

Expand table

TryCreate(Uri, Uri, Uri)	Creates a new Uri using the specified base and relative Uri instances.
TryCreate(String, UriKind, Uri)	Creates a new Uri using the specified String instance and a UriKind.
TryCreate(String, UriCreationOptions, Uri)	Creates a new Uri using the specified String instance and UriCreationOptions.
TryCreate(Uri, String, Uri)	Creates a new Uri using the specified base and relative String instances.

TryCreate(Uri, Uri, Uri)

Creates a new Uri using the specified base and relative Uri instances.

C#

```
public static bool TryCreate (Uri? baseUri, Uri? relativeUri, out Uri?
result);
```

Parameters

baseUri Uri

The base URI.

`relativeUri` Uri

The relative URI to add to the base Uri.

`result` Uri

When this method returns, contains a Uri constructed from `baseUri` and `relativeUri`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the Uri was successfully created; otherwise, `false`.

Exceptions

ArgumentNullException

`baseUri` is `null`.

Remarks

If this method returns `true`, the new Uri is in `result`.

This method constructs the URI, puts it in canonical form, and validates it. If an unhandled exception occurs, this method catches it. If you want to create a Uri and get exceptions use one of the Uri constructors.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryCreate(String, UriKind, Uri)

Creates a new Uri using the specified String instance and a UriKind.

```
C#

public static bool TryCreate (string? uriString, UriKind uriKind, out
Uri? result);
```

Parameters

`uriString` String

The string representation of the Uri.

`uriKind` UriKind

The type of the Uri.

`result` Uri

When this method returns, contains the constructed Uri.

Returns

Boolean

`true` if the Uri was successfully created; otherwise, `false`.

Remarks

If this method returns `true`, the new Uri is in `result`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryCreate(String, UriCreationOptions, Uri)

Creates a new Uri using the specified String instance and UriCreationOptions.

```
C#

public static bool TryCreate (string? uriString, in UriCreationOptions
creationOptions, out Uri? result);
```

Parameters

`uriString` String

The string representation of the Uri.

`creationOptions` UriCreationOptions

Options that control how the Uri is created and behaves.

`result` Uri

When this method returns, contains the constructed Uri.

Returns

Boolean

`true` if the Uri was successfully created; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	6, 7, 8, 9

TryCreate(Uri, String, Uri)

Creates a new Uri using the specified base and relative String instances.

```
C#

public static bool TryCreate (Uri? baseUri, string? relativeUri, out Uri?
```

```
result);
```

Parameters

`baseUri` Uri

The base URI.

`relativeUri` String

The string representation of the relative URI to add to the base Uri.

`result` Uri

When this method returns, contains a Uri constructed from `baseUri` and `relativeUri`. This parameter is passed uninitialized.

Returns

Boolean

`true` if the Uri was successfully created; otherwise, `false`.

Remarks

If this method returns `true`, the new Uri is in `result`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.TryFormat(Span<Char>, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Attempts to format a canonical string representation for the Uri instance into the specified span.

C#

```
public bool TryFormat (Span<char> destination, out int charsWritten);
```

Parameters

destination Span<Char>

The span into which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Applies to

Product	Versions
.NET	8, 9

Uri.Unescape(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> Uri.Unescape has been deprecated. Use GetComponents() or Uri.UnescapeDataString() to unescape a Uri component or a string.

Converts the specified string by replacing any escape sequences with their unescaped representation.

C#

```
[System.Obsolete("Uri.Unescape has been deprecated. Use GetComponents() or Uri.UnescapeDataString() to unescape a Uri component or a string.")]
protected virtual string Unescape (string path);
```

Parameters

`path` String

The string to convert.

Returns

String

The unescaped value of the `path` parameter.

Attributes ObsoleteAttribute

Applies to

Product	Versions *(Obsolete)*
.NET	*(Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9)*
.NET Framework	1.1 *(2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1)*

Uri.UnescapeDataString(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts a string to its unescaped representation.

C#

```
public static string UnescapeDataString (string stringToUnescape);
```

Parameters

stringToUnescape String

The string to unescape.

Returns

String

The unescaped representation of `stringToUnescape`.

Exceptions

ArgumentNullException

`stringToUnescape` is `null`.

Examples

The following code example unescapes a URI, and then converts any plus characters ("+") into spaces.

C#

```
String DataString = Uri.UnescapeDataString(".NET+Framework");
Console.WriteLine("Unescaped string: {0}", DataString);
```

```
String PlusString = DataString.Replace('+',' ');
Console.WriteLine("plus to space string: {0}", PlusString);
```

Remarks

You should use this method with care. Unescaping a string that has been previously unescaped can lead to ambiguities and errors.

Many Web browsers escape spaces inside of URIs into plus ("+") characters; however, the UnescapeDataString method does not convert plus characters into spaces because this behavior is not standard across all URI schemes.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.Equality(Uri, Uri) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two Uri instances have the same value.

```
C#
public static bool operator == (Uri? uri1, Uri? uri2);
```

Parameters

uri1 Uri

A URI to compare with `uri2`.

uri2 Uri

A URI to compare with `uri1`.

Returns

Boolean

`true` if the Uri instances are equivalent; otherwise, `false`.

Examples

This example creates three Uri instances from strings and compares them to determine whether they represent the same value. `Address1` and `Address2` are the same because the Fragment portion is ignored for this comparison. The outcome is written to the console.

```
C#
// Create some Uris.
Uri address1 = new Uri("http://www.contoso.com/index.htm#search");
Uri address2 = new Uri("http://www.contoso.com/index.htm");
Uri address3 = new Uri("http://www.contoso.com/index.htm?date=today");
```

```
// The first two are equal because the fragment is ignored.
if (address1 == address2)
    Console.WriteLine("{0} is equal to {1}", address1.ToString(),
address2.ToString());

// The second two are not equal.
if (address2 != address3)
    Console.WriteLine("{0} is not equal to {1}", address2.ToString(),
address3.ToString());
```

Remarks

This overload uses the Equals method to determine whether the two Uri instances are equivalent. UserInfo and Fragment content is ignored when making this comparison.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Uri.Inequality(Uri, Uri) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two Uri instances do not have the same value.

```
C#
public static bool operator != (Uri? uri1, Uri? uri2);
```

Parameters

uri1 Uri

A URI to compare with `uri2`.

uri2 Uri

A URI to compare with `uri1`.

Returns

Boolean

`true` if the two Uri instances are not equal; otherwise, `false`. If either parameter is `null`, this method returns `true`.

Examples

This example creates three Uri instances from strings and compares them to determine whether they represent the same value. `Address2` and `Address3` are not the same because `Address3` contains a Query that is not found in `Address2`. The outcome is written to the console.

```
C#
// Create some Uris.
Uri address1 = new Uri("http://www.contoso.com/index.htm#search");
```

```
Uri address2 = new Uri("http://www.contoso.com/index.htm");
Uri address3 = new Uri("http://www.contoso.com/index.htm?date=today");

// The first two are equal because the fragment is ignored.
if (address1 == address2)
    Console.WriteLine("{0} is equal to {1}", address1.ToString(),
address2.ToString());

// The second two are not equal.
if (address2 != address3)
    Console.WriteLine("{0} is not equal to {1}", address2.ToString(),
address3.ToString());
```

Remarks

This overload uses the Equals method to determine whether the two Uri instances are not equivalent. UserInfo and Fragment content is ignored when making this comparison.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Uri.IFormattable.ToString(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Formats the value of the current instance using the specified format.

C#

```
string IFormattable.ToString (string format, IFormatProvider
formatProvider);
```

Parameters

`format` String

The format to use. -or- A `null` reference (`Nothing` in Visual Basic) to use the default format defined for the type of the IFormattable implementation.

`formatProvider` IFormatProvider

The provider to use to format the value. -or- A `null` reference (`Nothing` in Visual Basic) to obtain the numeric format information from the current locale setting of the operating system.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Uri.ISpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance into the provided span of characters.

C#

```
bool ISpanFormattable.TryFormat (Span<char> destination, out int
charsWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Collaborate with us on GitHub

Uri.ISerializable.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the data needed to serialize the current instance.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo serializationInfo,
System.Runtime.Serialization.StreamingContext streamingContext);
```

Parameters

`serializationInfo` SerializationInfo

The information required to serialize the Uri.

`streamingContext` StreamingContext

An object containing the source and destination of the serialized stream associated with the Uri.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriBuilder Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides a custom constructor for uniform resource identifiers (URIs) and modifies URIs for the Uri class.

C#

```
public class UriBuilder
```

Inheritance Object → UriBuilder

Remarks

The UriBuilder class provides a convenient way to modify the contents of a Uri instance without creating a new Uri instance for each modification.

The UriBuilder properties provide read/write access to the read-only Uri properties so that they can be modified.

Constructors

Expand table

UriBuilder()	Initializes a new instance of the UriBuilder class.
UriBuilder(String)	Initializes a new instance of the UriBuilder class with the specified URI.
UriBuilder(String, String)	Initializes a new instance of the UriBuilder class with the specified scheme and host.
UriBuilder(String, String, Int32)	Initializes a new instance of the UriBuilder class with the specified scheme, host, and port.
UriBuilder(String, String,	Initializes a new instance of the UriBuilder class with the specified

Int32, String)	scheme, host, port number, and path.
UriBuilder(String, String, Int32, String, String)	Initializes a new instance of the UriBuilder class with the specified scheme, host, port number, path, and query string or fragment identifier.
UriBuilder(Uri)	Initializes a new instance of the UriBuilder class with the specified Uri instance.

Properties

Expand table

Fragment	Gets or sets the fragment portion of the URI, including the leading '#' character if not empty.
Host	Gets or sets the Domain Name System (DNS) host name or IP address of a server.
Password	Gets or sets the password associated with the user that accesses the URI.
Path	Gets or sets the path to the resource referenced by the URI.
Port	Gets or sets the port number of the URI.
Query	Gets or sets any query information included in the URI, including the leading '?' character if not empty.
Scheme	Gets or sets the scheme name of the URI.
Uri	Gets the Uri instance constructed by the specified UriBuilder instance.
User Name	Gets or sets the user name associated with the user that accesses the URI.

Methods

Expand table

Equals(Object)	Compares an existing Uri instance with the contents of the UriBuilder for equality.
GetHashCode()	Returns the hash code for the URI.
GetType()	Gets the Type of the current instance. (Inherited from Object)
Memberwise	Creates a shallow copy of the current Object.

Clone()	(Inherited from Object)
ToString()	Returns the display string for the specified UriBuilder instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the UriBuilder class.

Overloads

Expand table

UriBuilder()	Initializes a new instance of the UriBuilder class.
UriBuilder(String)	Initializes a new instance of the UriBuilder class with the specified URI.
UriBuilder(Uri)	Initializes a new instance of the UriBuilder class with the specified Uri instance.
UriBuilder(String, String)	Initializes a new instance of the UriBuilder class with the specified scheme and host.
UriBuilder(String, String, Int32)	Initializes a new instance of the UriBuilder class with the specified scheme, host, and port.
UriBuilder(String, String, Int32, String)	Initializes a new instance of the UriBuilder class with the specified scheme, host, port number, and path.
UriBuilder(String, String, Int32, String, String)	Initializes a new instance of the UriBuilder class with the specified scheme, host, port number, path, and query string or fragment identifier.

UriBuilder()

Initializes a new instance of the UriBuilder class.

C#

```
public UriBuilder ();
```

Remarks

The parameterless constructor creates a new instance of the UriBuilder class with its properties initialized as follows.

Expand table

Property	Initial Value
Fragment	Empty
Host	"loopback"
Password	Empty
Path	"/"
Port	-1
Query	Empty
Scheme	"http"
UserName	Empty

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder(String)

Initializes a new instance of the UriBuilder class with the specified URI.

```
C#
```

```
public UriBuilder (string uri);
```

Parameters

`uri` String

A URI string.

Exceptions

ArgumentNullException

`uri` is `null`.

UriFormatException

`uri` is a zero-length string or contains only spaces.

-or-

The parsing routine detected a scheme in an invalid form.

-or-

The parser detected more than two consecutive slashes in a URI that does not use the "file" scheme.

-or-

`uri` is not a valid URI.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

Remarks

This constructor initializes a new instance of the UriBuilder class with the Fragment, Host, Path, Port, Query, Scheme, and Uri properties set as specified in `uri`.

If `uri` does not specify a scheme, the scheme defaults to "http:".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder(Uri)

Initializes a new instance of the UriBuilder class with the specified Uri instance.

C#

```
public UriBuilder (Uri uri);
```

Parameters

`uri` Uri

An instance of the Uri class.

Exceptions

ArgumentNullException

`uri` is `null`.

Remarks

This constructor initializes a new instance of the UriBuilder class with the Fragment, Host, Path, Port, Query, Scheme, and Uri properties set as specified in `uri`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7,

Product	Versions
	8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder(String, String)

Initializes a new instance of the UriBuilder class with the specified scheme and host.

```
C#

public UriBuilder (string? schemeName, string? hostName);
```

Parameters

`schemeName` String

An Internet access protocol.

`hostName` String

A DNS-style domain name or IP address.

Examples

The following example creates a UriBuilder instance that contains the URI `http://www.contoso.com/`.

```
C#

UriBuilder myUri = new UriBuilder("http","www.contoso.com");
```

Remarks

The UriBuilder instance is initialized with the Scheme property set to `schemeName` and the Host property set to `hostName`. Port is initialized to the value -1 to indicate the default port for the scheme should be used, and the Path property is set to the slash character (/).

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder(String, String, Int32)

Initializes a new instance of the UriBuilder class with the specified scheme, host, and port.

C#

```
public UriBuilder (string? scheme, string? host, int portNumber);
```

Parameters

`scheme` String

An Internet access protocol.

`host` String

A DNS-style domain name or IP address.

`portNumber` Int32

An IP port number for the service.

Exceptions

ArgumentOutOfRangeException

`portNumber` is less than -1 or greater than 65,535.

Examples

The following example creates a UriBuilder instance that contains the URI `http://www.contoso.com:8080/`.

```
C#

UriBuilder myUri = new UriBuilder("http","www.contoso.com",8080);
```

Remarks

The UriBuilder instance is initialized with the Scheme property set to `schemeName`, the Host property set to `hostName`, and the Port property set to `portNumber`. The Path property is set to the slash character (/).

If the `portNumber` is set to a value of -1, this indicates that the default port value for the scheme will be used to connect to the host.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder(String, String, Int32, String)

Initializes a new instance of the UriBuilder class with the specified scheme, host, port number, and path.

```
C#

public UriBuilder (string? scheme, string? host, int port, string?
pathValue);
```

Parameters

`scheme` String

An Internet access protocol.

`host` String

A DNS-style domain name or IP address.

`port` Int32

An IP port number for the service.

`pathValue` String

The path to the Internet resource.

Exceptions

ArgumentOutOfRangeException

`port` is less than -1 or greater than 65,535.

Examples

The following example creates a UriBuilder instance that contains the URI `http://www.contoso.com:8080/index.htm`.

```
C#

UriBuilder myUri = new
UriBuilder("http","www.contoso.com",8080,"index.htm");
```

Remarks

The UriBuilder instance is initialized with the Scheme property set to `schemeName`, the Host property set to `hostName`, the Port property set to `portNumber`, and the Path property set to `pathValue`.

If the `portNumber` is set to a value of -1, this indicates that the default port value for the scheme will be used to connect to the host.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder(String, String, Int32, String, String)

Initializes a new instance of the UriBuilder class with the specified scheme, host, port number, path, and query string or fragment identifier.

C#

```
public UriBuilder (string? scheme, string? host, int port, string? path,
string? extraValue);
```

Parameters

`scheme` String

An Internet access protocol.

`host` String

A DNS-style domain name or IP address.

`port` Int32

An IP port number for the service.

`path` String

The path to the Internet resource.

`extraValue` String

A query string or fragment identifier.

Exceptions

ArgumentException

`extraValue` is neither `null` nor Empty, nor does a valid fragment identifier begin with a number sign (#), nor a valid query string begin with a question mark (?).

ArgumentOutOfRangeException

`port` is less than -1 or greater than 65,535.

Examples

The following example creates a UriBuilder instance that contains the URI `http://www.contoso.com:8080/index.htm#top`.

```
C#

UriBuilder myUri = new
UriBuilder("http","www.contoso.com",8080,"index.htm","#top");
```

Remarks

The UriBuilder instance is initialized with the Scheme property set to `schemeName`, the Host property set to `hostName`, the Port property set to `portNumber`, and the Path property set to `pathValue`. If `extraValue` begins with a number sign (#), then Fragment is set to `extraValue`. If `extraValue` begins with a question mark (?), then Query is set to `extraValue`.

If the `portNumber` is set to a value of -1, this indicates that the default port value for the scheme will be used to connect to the host.

Applies to

UriBuilder.Fragment Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the fragment portion of the URI, including the leading '#' character if not empty.

```
C#

public string Fragment { get; set; }
```

Property Value

String

The fragment portion of the URI.

Examples

The following example creates the URI `"http://www.contoso.com/index.htm#main"`.

```
C#

UriBuilder uBuild = new UriBuilder("http://www.contoso.com/");
uBuild.Path = "index.htm";
uBuild.Fragment = "main";

Uri myUri = uBuild.Uri;
```

Remarks

The Fragment property contains any text following a fragment marker (#) in the URI, including the marker itself. When setting the Fragment property:

- In .NET Framework, the fragment marker is always prepended to the string, even if one is already present.

- In .NET 5 (and .NET Core) and later versions, the fragment marker is prepended to the string if it's not already present.

> **Note**
>
> To append a value to an existing fragment in .NET Framework, you must remove the leading fragment marker before setting the property with the new value. This is because .NET Framework always prepends the fragment marker when setting the property. .NET 5 (and .NET Core) and later versions are tolerant to a leading fragment marker, and will only prepend one if necessary.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UriBuilder.Host Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the Domain Name System (DNS) host name or IP address of a server.

C#

```
public string Host { get; set; }
```

Property Value

String

The DNS host name or IP address of the server.

Remarks

The Host property contains the fully qualified DNS host name or IP address of the server.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UriBuilder.Password Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the password associated with the user that accesses the URI.

C#

```
public string Password { get; set; }
```

Property Value

String

The password of the user that accesses the URI.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

more information, see our contributor guide.

UriBuilder.Path Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the path to the resource referenced by the URI.

```
C#
public string Path { get; set; }
```

Property Value

String

The path to the resource referenced by the URI.

Remarks

The Path property contains the path information that the server uses to resolve requests for information. Typically, this is the path to the desired information on the server's file system. It can also indicate the application or script that the server must run to provide the information.

The path information does not include the scheme, host name, or query portion of the URI. The Path property always returns at least a slash (/).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder.Port Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the port number of the URI.

```
C#
public int Port { get; set; }
```

Property Value

Int32

The port number of the URI.

Exceptions

ArgumentOutOfRangeException

The port cannot be set to a value less than -1 or greater than 65,535.

Remarks

The port number defines the protocol port for contacting the host referenced in the URI. If a port is not specified as part of the URI, the Port property returns the value of -1 to indicate that the default port value for the protocol scheme will be used to connect to the host. If the Port property is set to a value of -1, this indicates that the default port value for the protocol scheme will be used to connect to the host.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder.Query Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets any query information included in the URI, including the leading '?' character if not empty.

```
C#

public string Query { get; set; }
```

Property Value

String

The query information included in the URI.

Examples

The following example sets the Query property.

```
C#

UriBuilder baseUri = new UriBuilder("http://www.contoso.com/default.aspx?
Param1=7890");
string queryToAppend = "param2=1234";

if (baseUri.Query != null && baseUri.Query.Length > 1)
    // Note: In .NET Core and .NET 5+, you can simplify by removing
    // the call to Substring(), which removes the leading "?" character.
    baseUri.Query = baseUri.Query.Substring(1) + "&" + queryToAppend;
else
    baseUri.Query = queryToAppend;
```

Remarks

The Query property contains any query information included in the URI. Query information is separated from the path information by a question mark (?) and continues to the end of the URI. The query information that's returned includes the leading question mark. When setting the Query property:

- In .NET Framework, a question mark is always prepended to the string, even if the string already starts with a question mark.
- In .NET 5 (and .NET Core) and later versions, a question mark is prepended to the string if it's not already present.

The query information is escaped according to RFC 2396.

> **Note**
>
> To append a value to existing query information in .NET Framework, you must remove the leading question mark before setting the property with the new value. This is because .NET Framework always prepends the question mark when setting the property. .NET 5 (and .NET Core) and later versions are tolerant to a leading question mark, and will only prepend one if necessary.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder.Scheme Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the scheme name of the URI.

C#

```
public string Scheme { get; set; }
```

Property Value

String

The scheme of the URI.

Exceptions

ArgumentException

The scheme cannot be set to an invalid scheme name.

Remarks

The following table lists the valid scheme names for the Scheme property.

Expand table

Scheme	Description
file	The resource is a file on the local computer.
ftp	The resource is accessed through FTP.
gopher	The resource is accessed through the Gopher protocol.
http	The resource is accessed through HTTP.
https	The resource is accessed through SSL-encrypted HTTP.

Scheme	Description
mailto	The resource is an email address and is accessed through SMTP.
news	The resource is accessed through NNTP.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder.Uri Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the Uri instance constructed by the specified UriBuilder instance.

C#

```
public Uri Uri { get; }
```

Property Value

Uri

The URI constructed by the UriBuilder.

Exceptions

UriFormatException

The URI constructed by the UriBuilder properties is invalid.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

Remarks

The Uri property contains the Uri created by the UriBuilder. Any changes made to the UriBuilder properties are reflected in the Uri property.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriBuilder.UserName Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the user name associated with the user that accesses the URI.

C#

```
public string UserName { get; set; }
```

Property Value

String

The name of the user that accesses the URI.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UriBuilder.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares an existing Uri instance with the contents of the UriBuilder for equality.

C#

```
public override bool Equals (object? rparam);
```

Parameters

`rparam` Object

The object to compare with the current instance.

Returns

Boolean

`true` if `rparam` represents the same Uri as the Uri constructed by this UriBuilder instance; otherwise, `false`.

Remarks

The Equals method compares a specified Uri instance with the Uri instance built by the UriBuilder instance. If the two are the same, the Equals method returns `true`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

UriBuilder.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the URI.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code generated for the URI.

Remarks

The hash code is generated without including any fragment. The URIs `http://www.contoso.com/index.htm#search` and `http://www.contoso.com/index.htm` generate the same hash code.

The hash codes for Uri A and B are guaranteed to be the same when A.Equals(B) is `true`.

This method implements Object.GetHashCode.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriBuilder.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the display string for the specified UriBuilder instance.

C#

```
public override string ToString ();
```

Returns

String

The string that contains the unescaped display string of the UriBuilder.

Exceptions

UriFormatException

The UriBuilder instance has a bad password.

Note: In .NET for Windows Store apps or the Portable Class Library, catch the base class exception, FormatException, instead.

Remarks

The display string contains the Port property value if one of the following conditions is true:

- The Port property was set.
- The port was specified when the UriBuilder was constructed using one of the UriBuilder constructors that accept a port number parameter.

In either case, the display string does not contain the Port property value if the port number was set to a value of -1 (for the default port).

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UriComponents Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies the parts of a Uri.

This enumeration supports a bitwise combination of its member values.

C#

```
[System.Flags]
public enum UriComponents
```

Inheritance Object → ValueType → Enum → UriComponents

Attributes FlagsAttribute

Fields

Expand table

AbsoluteUri	127	The Scheme, UserInfo, Host, Port, LocalPath, Query, and Fragment data.
Fragment	64	The Fragment data.
Host	4	The Host data.
HostAndPort	132	The Host and Port data. If no port data is in the Uri and a default port has been assigned to the Scheme, the default port is returned. If there is no default port, -1 is returned.
HttpRequestUrl	61	The Scheme, Host, Port, LocalPath, and Query data.
KeepDelimiter	1073741824	Specifies that the delimiter should be included.
NormalizedHost	256	The normalized form of the Host.
Path	16	The LocalPath data.

PathAndQuery	48	The LocalPath and Query data. Also see PathAndQuery.
Port	8	The Port data.
Query	32	The Query data.
Scheme	1	The Scheme data.
SchemeAndServer	13	The Scheme, Host, and Port data.
SerializationInfoString	-2147483648	The complete Uri context that is needed for Uri Serializers. The context includes the IPv6 scope.
StrongAuthority	134	The UserInfo, Host, and Port data. If no port data is in the Uri and a default port has been assigned to the Scheme, the default port is returned. If there is no default port, -1 is returned.
StrongPort	128	The Port data. If no port data is in the Uri and a default port has been assigned to the Scheme, the default port is returned. If there is no default port, -1 is returned.
UserInfo	2	The UserInfo data.

Remarks

This enumeration is used to identify the parts of a Uri. This enumeration is used with the Uri.GetComponents method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriFormat Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Controls how URI information is escaped.

```
C#

public enum UriFormat
```

Inheritance Object → ValueType → Enum → UriFormat

Fields

Expand table

SafeUnescaped	3	Characters that have a reserved meaning in the requested URI components remain escaped. All others are not escaped.
Unescaped	2	No escaping is performed.
UriEscaped	1	Escaping is performed according to the rules in RFC 2396.

Remarks

This enumeration is used by the GetComponents method to specify the level of character escaping in the returned URI.

RFC 2396 defines the standard escaping for URIs, and is available at https://rfc-editor.org.

SafeUnescaped leaves the following characters escaped if the character has a reserved meaning in the requested UriComponents: "%", "#", "?", "/", "\", and "@".

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriFormatException Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

The exception that is thrown when an invalid Uniform Resource Identifier (URI) is detected.

```
C#
public class UriFormatException : FormatException
```

Inheritance Object → Exception → SystemException → FormatException → UriFormatException

Implements ISerializable

Remarks

The UriFormatException is thrown by the Uri class constructor if the supplied URI could not be correctly parsed. The format for a valid URI is defined in RFC 2396.

The text of the Message property indicates the reason that the exception was thrown.

> **Note**
>
> This exception is not included in the **.NET for Windows Store apps** or the **Portable Class Library**, but it is thrown by some members that are. To catch the exception in that case, write a `catch` statement for **FormatException** instead.

Constructors

Expand table

UriFormatException()	Initializes a new instance of the UriFormatException class.

UriFormatException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the UriFormatException class from the specified SerializationInfo and StreamingContext instances.
UriFormatException(String)	Initializes a new instance of the UriFormatException class with the specified message.
UriFormatException(String, Exception)	Initializes a new instance of the UriFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

Properties

Expand table

Data	Gets a collection of key/value pairs that provide additional user-defined information about the exception. (Inherited from Exception)
HelpLink	Gets or sets a link to the help file associated with this exception. (Inherited from Exception)
HResult	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception. (Inherited from Exception)
Inner Exception	Gets the Exception instance that caused the current exception. (Inherited from Exception)
Message	Gets a message that describes the current exception. (Inherited from Exception)
Source	Gets or sets the name of the application or the object that causes the error. (Inherited from Exception)
StackTrace	Gets a string representation of the immediate frames on the call stack. (Inherited from Exception)
TargetSite	Gets the method that throws the current exception. (Inherited from Exception)

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetBaseException()	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. (Inherited from Exception)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** When overridden in a derived class, sets the SerializationInfo with information about the exception. (Inherited from Exception)
GetType()	Gets the runtime type of the current instance. (Inherited from Exception)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Creates and returns a string representation of the current exception. (Inherited from Exception)

Events

Expand table

SerializeObjectState	**Obsolete.** Occurs when an exception is serialized to create an exception state object that contains serialized data about the exception. (Inherited from Exception)

Explicit Interface Implementations

Expand table

ISerializable.GetObjectData(SerializationInfo, StreamingContext)	Populates a SerializationInfo instance with the data that is needed to serialize the UriFormatException.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriFormatException Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the UriFormatException class.

Overloads

Expand table

UriFormatException()	Initializes a new instance of the UriFormatException class.
UriFormatException(String)	Initializes a new instance of the UriFormatException class with the specified message.
UriFormatException(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the UriFormatException class from the specified SerializationInfo and StreamingContext instances.
UriFormatException(String, Exception)	Initializes a new instance of the UriFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

UriFormatException()

Initializes a new instance of the UriFormatException class.

C#

```
public UriFormatException ();
```

Remarks

The parameterless constructor initializes a new instance of the UriFormatException class with all fields set to `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriFormatException(String)

Initializes a new instance of the UriFormatException class with the specified message.

C#

```
public UriFormatException (string? textString);
```

Parameters

`textString` String

The error message string.

Remarks

The UriFormatException constructor initializes the UriFormatException instance with the Message property set to the value of `textString`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriFormatException(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the UriFormatException class from the specified SerializationInfo and StreamingContext instances.

C#

```
[System.Obsolete("This API supports obsolete formatter-based
serialization. It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-
warnings/{0}")]
protected UriFormatException
(System.Runtime.Serialization.SerializationInfo serializationInfo,
System.Runtime.Serialization.StreamingContext streamingContext);
```

Parameters

`serializationInfo` SerializationInfo

A SerializationInfo that contains the information that is required to serialize the new UriFormatException.

`streamingContext` StreamingContext

A StreamingContext that contains the source of the serialized stream that is associated with the new UriFormatException.

Attributes ObsoleteAttribute

Remarks

This constructor implements the ISerializable interface for the UriFormatException class.

See also

- ISerializable

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriFormatException(String, Exception)

Initializes a new instance of the UriFormatException class with a specified error message and a reference to the inner exception that is the cause of this exception.

C#

```
public UriFormatException (string? textString, Exception? e);
```

Parameters

`textString` String

The message that describes the exception. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

`e` Exception

The exception that is the cause of the current exception. If the `innerException` parameter is not `null`, the current exception is raised in a `catch` block that handles the inner exception.

Remarks

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the InnerException property. The InnerException property returns the same value that is passed into the constructor, or `null` if the InnerException property does not supply the inner exception value to the constructor.

The following table shows the initial property values for an instance of UriFormatException.

Expand table

Property	Value
InnerException	`null`.
Message	The error message string specified in `message`.

UriFormatException.ISerializable.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Populates a SerializationInfo instance with the data that is needed to serialize the UriFormatException.

C#

```
void ISerializable.GetObjectData
(System.Runtime.Serialization.SerializationInfo serializationInfo,
System.Runtime.Serialization.StreamingContext streamingContext);
```

Parameters

`serializationInfo` SerializationInfo

A SerializationInfo that will hold the serialized data for the UriFormatException.

`streamingContext` StreamingContext

A StreamingContext that contains the destination of the serialized stream that is associated with the new UriFormatException.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriHostNameType Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines host name types for the CheckHostName(String) method.

C#

```
public enum UriHostNameType
```

Inheritance Object → ValueType → Enum → UriHostNameType

Fields

Expand table

Basic	1	The host is set, but the type cannot be determined.
Dns	2	The host name is a domain name system (DNS) style host name.
IPv4	3	The host name is an Internet Protocol (IP) version 4 host address.
IPv6	4	The host name is an Internet Protocol (IP) version 6 host address.
Unknown	0	The type of the host name is not supplied.

Remarks

The UriHostNameType enumeration defines the values that the Uri.CheckHostName method can return.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriKind Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines the different kinds of URIs.

C#

```
public enum UriKind
```

Inheritance Object → ValueType → Enum → UriKind

Fields

Expand table

Absolute	1	The URI is absolute.
Relative	2	The URI is relative.
RelativeOrAbsolute	0	The URI kind is indeterminate.

Remarks

Absolute URIs are characterized by a complete reference to the resource (example: `http://www.contoso.com/index.html`), while a relative URI depends on a previously defined base URI (example: `/index.html`).

The following list shows some APIs that use the `UriKind` enum:

- Uri.Uri(String, UriKind)
- Uri.IsWellFormedUriString(String, UriKind)
- Uri.TryCreate(String, UriKind, Uri)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

UriParser Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Parses a new URI scheme. This is an abstract class.

```
C#
public abstract class UriParser
```

Inheritance Object → UriParser

Derived System.FileStyleUriParser
System.FtpStyleUriParser
System.GenericUriParser
System.GopherStyleUriParser
System.HttpStyleUriParser
More...

Remarks

The UriParser class enables you to create parsers for new URI schemes. You can write these parsers in their entirety, or the parsers can be derived from well-known schemes (HTTP, FTP, and other schemes based on network protocols). If you want to create a completely new parser, inherit from GenericUriParser. If you want to create a parser that extends a well-known URI scheme, inherit from FtpStyleUriParser, HttpStyleUriParser, FileStyleUriParser, GopherStyleUriParser, or LdapStyleUriParser.

Microsoft strongly recommends that you use a parser shipped with .NET. Building your own parser increases the complexity of your application, and will not perform as well as the shipped parsers.

Constructors

Expand table

UriParser()	Constructs a default URI parser.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetComponents(Uri, UriComponents, UriFormat)	Gets the components from a URI.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetType()	Gets the Type of the current instance. (Inherited from Object)
InitializeAndValidate(Uri, UriFormatException)	Initialize the state of the parser and validate the URI.
IsBaseOf(Uri, Uri)	Determines whether `baseUri` is a base URI for `relativeUri`.
IsKnownScheme(String)	Indicates whether the parser for a scheme is registered.
IsWellFormedOriginalString(Uri)	Indicates whether a URI is well-formed.
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
OnNewUri()	Invoked by a Uri constructor to get a UriParser instance.
OnRegister(String, Int32)	Invoked by the Framework when a UriParser method is registered.
Register(UriParser, String, Int32)	Associates a scheme and port number with a UriParser.
Resolve(Uri, Uri, UriFormatException)	Called by Uri constructors and TryCreate to resolve a relative URI.
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UriParser Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Constructs a default URI parser.

C#

```
protected UriParser ();
```

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriParser.GetComponents(Uri, UriComponents, UriFormat) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the components from a URI.

```
C#

protected virtual string GetComponents (Uri uri, UriComponents components,
UriFormat format);
```

Parameters

`uri` Uri

The URI to parse.

`components` UriComponents

The UriComponents to retrieve from `uri`.

`format` UriFormat

One of the UriFormat values that controls how special characters are escaped.

Returns

String

A string that contains the components.

Exceptions

ArgumentOutOfRangeException

`uriFormat` is invalid.

-or-

`uriComponents` is not a combination of valid UriComponents values.

InvalidOperationException
`uri` requires user-driven parsing

-or-

`uri` is not an absolute URI. Relative URIs cannot be used with this method.

Remarks

Use the GetComponents method to determine the value of various parts of the URI, such as the Scheme, Host, or Port.

The components are returned in the order that they appear in the URI. For example, if Scheme is specified, it appears first.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriParser.InitializeAndValidate(Uri, UriFormatException) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initialize the state of the parser and validate the URI.

C#

```
protected virtual void InitializeAndValidate (Uri uri, out
UriFormatException? parsingError);
```

Parameters

`uri` Uri

The Uri to validate.

`parsingError` UriFormatException

When this method returns, contains the validation errors, if any.

Remarks

The InitializeAndValidate method is called every time a Uri is instantiated.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriParser.IsBaseOf(Uri, Uri) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether `baseUri` is a base URI for `relativeUri`.

C#

```
protected virtual bool IsBaseOf (Uri baseUri, Uri relativeUri);
```

Parameters

`baseUri` Uri

The base URI.

`relativeUri` Uri

The URI to test.

Returns

Boolean

`true` if `baseUri` is a base URI for `relativeUri`; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriParser.IsKnownScheme(String) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether the parser for a scheme is registered.

C#

```
public static bool IsKnownScheme (string schemeName);
```

Parameters

schemeName String

The scheme name to check.

Returns

Boolean

`true` if `schemeName` has been registered; otherwise, `false`.

Exceptions

ArgumentNullException

The `schemeName` parameter is null.

ArgumentOutOfRangeException

The `schemeName` parameter is not valid.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriParser.IsWellFormedOriginalString(Uri) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether a URI is well-formed.

```
C#
protected virtual bool IsWellFormedOriginalString (Uri uri);
```

Parameters

`uri` Uri

The URI to check.

Returns

Boolean

`true` if `uri` is well-formed; otherwise, `false`.

Remarks

The IsWellFormedOriginalString method will return false if:

- The string is not correctly escaped per RFC 2396.
- The string represents an absolute URI that references an implicit file URI.
- The string represents an absolute URI that is missing a forward slash before the path component.
- The string contains unescaped backslashes, even if they will be treated as forward slashes.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriParser.OnNewUri Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Invoked by a Uri constructor to get a UriParser instance.

C#

```
protected virtual UriParser OnNewUri ();
```

Returns

UriParser

A UriParser for the constructed Uri.

Remarks

The default implementation returns the same UriParser instance. You may need to override this method and return a different UriParser for each invocation if you are operating in a multithreaded environment.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriParser.OnRegister(String, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Invoked by the Framework when a UriParser method is registered.

C#

```
protected virtual void OnRegister (string schemeName, int defaultPort);
```

Parameters

`schemeName` String

The scheme that is associated with this UriParser.

`defaultPort` Int32

The port number of the scheme.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriParser.Register(UriParser, String, Int32) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Associates a scheme and port number with a UriParser.

```
C#

public static void Register (UriParser uriParser, string schemeName, int
defaultPort);
```

Parameters

`uriParser` UriParser

The URI parser to register.

`schemeName` String

The name of the scheme that is associated with this parser.

`defaultPort` Int32

The default port number for the specified scheme.

Exceptions

ArgumentNullException

`uriParser` parameter is null

-or-

`schemeName` parameter is null.

ArgumentOutOfRangeException

`schemeName` parameter is not valid

-or-

`defaultPort` parameter is not valid. The `defaultPort` parameter is less than -1 or greater than 65,534.

Remarks

If the `defaultPort` parameter is set to -1, the Register method registers no default value for the port number.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriParser.Resolve(Uri, Uri, UriFormatException) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Called by Uri constructors and TryCreate to resolve a relative URI.

C#

```
protected virtual string? Resolve (Uri baseUri, Uri? relativeUri, out
UriFormatException? parsingError);
```

Parameters

`baseUri` Uri

A base URI.

`relativeUri` Uri

A relative URI.

`parsingError` UriFormatException

When this method returns, contains the errors that occurred during the resolve process, if any.

Returns

String

The string of the resolved relative Uri.

Exceptions

InvalidOperationException

`baseUri` parameter is not an absolute Uri

-or-

`baseUri` parameter requires user-driven parsing.

Remarks

Uri constructors and Uri.TryCreate use Resolve to construct a URI from `baseUri` and `relativeUri`.

If a parsing error occurs, the returned string for the resolved relative Uri is null.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriPartial Enum

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Defines the parts of a URI for the GetLeftPart(UriPartial) method.

C#

```
public enum UriPartial
```

Inheritance Object → ValueType → Enum → UriPartial

Fields

Expand table

Authority	1	The scheme and authority segments of the URI.
Path	2	The scheme, authority, and path segments of the URI.
Query	3	The scheme, authority, path, and query segments of the URI.
Scheme	0	The scheme segment of the URI.

Remarks

The UriPartial enumeration defines the values that can be passed to the Uri.GetLeftPart method.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.0, 2.1

UriTypeConverter Class

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.TypeConverter.dll

Converts a String type to a Uri type, and vice versa.

C#

```
public class UriTypeConverter : System.ComponentModel.TypeConverter
```

Inheritance Object → TypeConverter → UriTypeConverter

Constructors

Expand table

UriTypeConverter()	Initializes a new instance of the UriTypeConverter class.

Methods

Expand table

CanConvertFrom(ITypeDescriptorContext, Type)	Returns whether this converter can convert an object of the given type to the type of this converter.
CanConvertFrom(Type)	Returns whether this converter can convert an object of the given type to the type of this converter. (Inherited from TypeConverter)
CanConvertTo(ITypeDescriptorContext, Type)	Returns whether this converter can convert the object to the specified type, using the specified context.
CanConvertTo(Type)	Returns whether this converter can convert the object to the specified type. (Inherited from TypeConverter)

ConvertFrom(ITypeDescriptorContext, CultureInfo, Object)	Converts the given object to the type of this converter, using the specified context and culture information.
ConvertFrom(Object)	Converts the given value to the type of this converter. (Inherited from TypeConverter)
ConvertFromInvariantString(ITypeDescriptorContext, String)	Converts the given string to the type of this converter, using the invariant culture and the specified context. (Inherited from TypeConverter)
ConvertFromInvariantString(String)	Converts the given string to the type of this converter, using the invariant culture. (Inherited from TypeConverter)
ConvertFromString(ITypeDescriptorContext, CultureInfo, String)	Converts the given text to an object, using the specified context and culture information. (Inherited from TypeConverter)
ConvertFromString(ITypeDescriptorContext, String)	Converts the given text to an object, using the specified context. (Inherited from TypeConverter)
ConvertFromString(String)	Converts the specified text to an object. (Inherited from TypeConverter)
ConvertTo(ITypeDescriptorContext, CultureInfo, Object, Type)	Converts a given value object to the specified type, using the specified context and culture information.
ConvertTo(Object, Type)	Converts the given value object to the specified type, using the arguments. (Inherited from TypeConverter)
ConvertToInvariantString(ITypeDescriptorContext, Object)	Converts the specified value to a culture-invariant string representation, using the specified context. (Inherited from TypeConverter)
ConvertToInvariantString(Object)	Converts the specified value to a culture-invariant string representation. (Inherited from TypeConverter)
ConvertToString(ITypeDescriptorContext, CultureInfo, Object)	Converts the given value to a string representation, using the specified context and culture information. (Inherited from TypeConverter)
ConvertToString(ITypeDescriptorContext, Object)	Converts the given value to a string representation, using the given context. (Inherited from TypeConverter)
ConvertToString(Object)	Converts the specified value to a string representation. (Inherited from TypeConverter)

CreateInstance(IDictionary)	Re-creates an Object given a set of property values for the object. (Inherited from TypeConverter)
CreateInstance(ITypeDescriptorContext, IDictionary)	Creates an instance of the type that this TypeConverter is associated with, using the specified context, given a set of property values for the object. (Inherited from TypeConverter)
Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
GetConvertFromException(Object)	Returns an exception to throw when a conversion cannot be performed. (Inherited from TypeConverter)
GetConvertToException(Object, Type)	Returns an exception to throw when a conversion cannot be performed. (Inherited from TypeConverter)
GetCreateInstanceSupported()	Returns whether changing a value on this object requires a call to the CreateInstance(IDictionary) method to create a new value. (Inherited from TypeConverter)
GetCreateInstanceSupported(ITypeDescriptorContext)	Returns whether changing a value on this object requires a call to CreateInstance(IDictionary) to create a new value, using the specified context. (Inherited from TypeConverter)
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetProperties(ITypeDescriptorContext, Object)	Returns a collection of properties for the type of array specified by the value parameter, using the specified context. (Inherited from TypeConverter)
GetProperties(ITypeDescriptorContext, Object, Attribute[])	Returns a collection of properties for the type of array specified by the value parameter, using the specified context and attributes. (Inherited from TypeConverter)
GetProperties(Object)	Returns a collection of properties for the type of array specified by the value parameter. (Inherited from TypeConverter)
GetPropertiesSupported()	Returns whether this object supports properties. (Inherited from TypeConverter)

GetPropertiesSupported(ITypeDescriptorContext)	Returns whether this object supports properties, using the specified context. (Inherited from TypeConverter)
GetStandardValues()	Returns a collection of standard values from the default context for the data type this type converter is designed for. (Inherited from TypeConverter)
GetStandardValues(ITypeDescriptorContext)	Returns a collection of standard values for the data type this type converter is designed for when provided with a format context. (Inherited from TypeConverter)
GetStandardValuesExclusive()	Returns whether the collection of standard values returned from GetStandardValues() is an exclusive list. (Inherited from TypeConverter)
GetStandardValuesExclusive(ITypeDescriptorContext)	Returns whether the collection of standard values returned from GetStandardValues() is an exclusive list of possible values, using the specified context. (Inherited from TypeConverter)
GetStandardValuesSupported()	Returns whether this object supports a standard set of values that can be picked from a list. (Inherited from TypeConverter)
GetStandardValuesSupported(ITypeDescriptorContext)	Returns whether this object supports a standard set of values that can be picked from a list, using the specified context. (Inherited from TypeConverter)
GetType()	Gets the Type of the current instance. (Inherited from Object)
IsValid(ITypeDescriptorContext, Object)	Returns whether the given value object is a Uri or a Uri can be created from it.
IsValid(Object)	Returns whether the given value object is valid for this type. (Inherited from TypeConverter)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
SortProperties(PropertyDescriptorCollection, String[])	Sorts a collection of properties. (Inherited from TypeConverter)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

UriTypeConverter.CanConvertFrom(ITypeDescriptorContext, Type) Method

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.TypeConverter.dll

Returns whether this converter can convert an object of the given type to the type of this converter.

C#

```
public override bool CanConvertFrom
(System.ComponentModel.ITypeDescriptorContext? context, Type sourceType);
```

Parameters

`context` ITypeDescriptorContext

An ITypeDescriptorContext that provides a format context.

`sourceType` Type

A Type that represents the type that you want to convert from.

Returns

Boolean

`true` if `sourceType` is a String type or a Uri type can be assigned from `sourceType`; otherwise, `false`.

Exceptions

ArgumentNullException

The `sourceType` parameter is `null`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriTypeConverter.CanConvertTo(ITypeDescriptorContext, Type) Method

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.TypeConverter.dll

Returns whether this converter can convert the object to the specified type, using the specified context.

C#

```
public override bool CanConvertTo
(System.ComponentModel.ITypeDescriptorContext? context, Type?
destinationType);
```

Parameters

`context` ITypeDescriptorContext

An ITypeDescriptorContext that provides a format context.

`destinationType` Type

A Type that represents the type that you want to convert to.

Returns

Boolean

`true` if `destinationType` is of type InstanceDescriptor, String, or Uri; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

UriTypeConverter.ConvertFrom Method

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.TypeConverter.dll

Converts the given object to the type of this converter, using the specified context and culture information.

C#

```
public override object? ConvertFrom
(System.ComponentModel.ITypeDescriptorContext? context,
System.Globalization.CultureInfo? culture, object value);
```

Parameters

`context` ITypeDescriptorContext

An ITypeDescriptorContext that provides a format context.

`culture` CultureInfo

The CultureInfo to use as the current culture.

`value` Object

The Object to convert.

Returns

Object

An Object that represents the converted value.

Exceptions

NotSupportedException

The conversion cannot be performed.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

UriTypeConverter.ConvertTo Method

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.TypeConverter.dll

Converts a given value object to the specified type, using the specified context and culture information.

```
C#

public override object ConvertTo
(System.ComponentModel.ITypeDescriptorContext? context,
System.Globalization.CultureInfo? culture, object? value, Type
destinationType);
```

Parameters

`context` ITypeDescriptorContext

An ITypeDescriptorContext that provides a format context.

`culture` CultureInfo

A CultureInfo. If `null` is passed, the current culture is assumed.

`value` Object

The Object to convert.

`destinationType` Type

The Type to convert the `value` parameter to.

Returns

Object

An Object that represents the converted value.

Exceptions

ArgumentNullException

The `destinationType` parameter is `null`.

NotSupportedException

The conversion cannot be performed.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

UriTypeConverter.IsValid(ITypeDescriptorContext, Object) Method

Reference

Definition

Namespace: System

Assembly: System.ComponentModel.TypeConverter.dll

Returns whether the given value object is a Uri or a Uri can be created from it.

```
C#

public override bool IsValid (System.ComponentModel.ITypeDescriptorContext?
context, object? value);
```

Parameters

`context` ITypeDescriptorContext

An ITypeDescriptorContext that provides a format context.

`value` Object

The Object to test for validity.

Returns

Boolean

`true` if `value` is a Uri or a String from which a Uri can be created; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions

ValueTuple Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides static methods for creating value tuples.

C#

```
public struct ValueTuple : IComparable, IComparable<ValueTuple>,
IEquatable<ValueTuple>, System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Inheritance Object → ValueType → ValueTuple

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple> , IEquatable<ValueTuple> , ITuple

Remarks

For more information about this API, see Value tuples.

Methods

Expand table

CompareTo(ValueTuple)	Compares the current ValueTuple instance to a specified ValueTuple instance.
Create()	Creates a new value tuple with zero components.
Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)	Creates a new value tuple with 8 components (an octuple).
Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Creates a new value tuple with 7 components (a septuple).

Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Creates a new value tuple with 6 components (a sexuple).
Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Creates a new value tuple with 5 components (a quintuple).
Create<T1,T2,T3,T4>(T1, T2, T3, T4)	Creates a new value tuple with 4 components (a quadruple).
Create<T1,T2,T3>(T1, T2, T3)	Creates a new value tuple with 3 components (a triple).
Create<T1,T2>(T1, T2)	Creates a new value tuple with 2 components (a pair).
Create<T1>(T1)	Creates a new value tuple with 1 component (a singleton).
Equals(Object)	Returns a value that indicates whether the current ValueTuple instance is equal to a specified object.
Equals(ValueTuple)	Determines whether two ValueTuple instances are equal. This method always returns `true`.
GetHashCode()	Returns the hash code for the current ValueTuple instance.
ToString()	Returns the string representation of this ValueTuple instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares this ValueTuple instance with a specified object and returns an indication of their relative values.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple instance to a specified object.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Returns the hash code for this ValueTuple instance.

ITuple.Item[Int32]	Returns an IndexOutOfRangeException. There are no elements in a `ValueTuple`.
ITuple.Length	Gets the length of this `ValueTuple` instance, which is always 0. There are no elements in a `ValueTuple`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple.CompareTo(ValueTuple) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple instance to a specified ValueTuple instance.

```
C#
public int CompareTo (ValueTuple other);
```

Parameters

`other` ValueTuple

The object to compare with the current instance.

Returns

Int32

This method always returns 0.

Implements

CompareTo(T)

Exceptions

ArgumentException

`other` is not a ValueTuple instance.

Remarks

Because a ValueTuple instance has no elements, any two ValueTuple instances are considered to be equivalent.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

ValueTuple.Create Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Creates a new value tuple instance.

Overloads

Expand table

Create()	Creates a new value tuple with zero components.
Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)	Creates a new value tuple with 8 components (an octuple).
Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Creates a new value tuple with 7 components (a septuple).
Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Creates a new value tuple with 6 components (a sexuple).
Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Creates a new value tuple with 5 components (a quintuple).
Create<T1,T2,T3,T4>(T1, T2, T3, T4)	Creates a new value tuple with 4 components (a quadruple).
Create<T1,T2,T3>(T1, T2, T3)	Creates a new value tuple with 3 components (a triple).
Create<T1,T2>(T1, T2)	Creates a new value tuple with 2 components (a pair).
Create<T1>(T1)	Creates a new value tuple with 1 component (a singleton).

Create()

Creates a new value tuple with zero components.

```
C#

public static ValueTuple Create ();
```

Returns

ValueTuple

A new value tuple with no components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8)

Creates a new value tuple with 8 components (an octuple).

```
C#

public static (T1, T2, T3, T4, T5, T6, T7, (T8))
Create<T1,T2,T3,T4,T5,T6,T7,T8> (T1 item1, T2 item2, T3 item3, T4 item4,
T5 item5, T6 item6, T7 item7, T8 item8);
```

Type Parameters

T1

The type of the value tuple's first component.

`T2`

The type of the value tuple's second component.

`T3`

The type of the value tuple's third component.

`T4`

The type of the value tuple's fourth component.

`T5`

The type of the value tuple's fifth component.

`T6`

The type of the value tuple's sixth component.

`T7`

The type of the value tuple's seventh component.

`T8`

The type of the value tuple's eighth component.

Parameters

`item1` T1

The value of the value tuple's first component.

`item2` T2

The value of the value tuple's second component.

`item3` T3

The value of the value tuple's third component.

`item4` T4

The value of the value tuple's fourth component.

`item5` T5

The value of the value tuple's fifth component.

`item6` T6

The value of the value tuple's sixth component.

`item7` T7

The value of the value tuple's seventh component.

`item8` T8

The value of the value tuple's eighth component.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7,ValueTuple<T8>>

A value tuple with 8 components.

Remarks

Create is a helper method that you can call to instantiate an 8-component value tuple without having to explicitly specify the types of its components.

> ⓘ **Note**
>
> You must call the **ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>** constructor to create a tuple with nine or more components unless your language provides a special syntax for this purpose. The static methods of the **ValueTuple** structure cannot be used to create a tuple with nine or more components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)

Creates a new value tuple with 7 components (a septuple).

```
C#

public static (T1, T2, T3, T4, T5, T6, T7) Create<T1,T2,T3,T4,T5,T6,T7>
(T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6, T7 item7);
```

Type Parameters

T1

The type of the value tuple's first component.

T2

The type of the value tuple's second component.

T3

The type of the value tuple's third component.

T4

The type of the value tuple's fourth component.

T5

The type of the value tuple's fifth component.

T6

The type of the value tuple's sixth component.

T7

The type of the value tuple's seventh component.

Parameters

item1 T1

The value of the value tuple's first component.

item2 T2

The value of the value tuple's second component.

`item3` T3

The value of the value tuple's third component.

`item4` T4

The value of the value tuple's fourth component.

`item5` T5

The value of the value tuple's fifth component.

`item6` T6

The value of the value tuple's sixth component.

`item7` T7

The value of the value tuple's seventh component.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6,T7>

A value tuple with 7 components.

Remarks

Create is a helper method that you can call to instantiate an 7-component value tuple without having to explicitly specify the types of its components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)

Creates a new value tuple with 6 components (a sexuple).

```
C#

public static (T1, T2, T3, T4, T5, T6) Create<T1,T2,T3,T4,T5,T6> (T1
item1, T2 item2, T3 item3, T4 item4, T5 item5, T6 item6);
```

Type Parameters

`T1`

The type of the value tuple's first component.

`T2`

The type of the value tuple's second component.

`T3`

The type of the value tuple's third component.

`T4`

The type of the value tuple's fourth component.

`T5`

The type of the value tuple's fifth component.

`T6`

The type of the value tuple's sixth component.

Parameters

`item1` T1

The value of the value tuple's first component.

`item2` T2

The value of the value tuple's second component.

`item3` T3

The value of the value tuple's third component.

`item4` T4

The value of the value tuple's fourth component.

`item5` T5

The value of the value tuple's fifth component.

`item6` T6

The value of the value tuple's sixth component.

Returns

ValueTuple<T1,T2,T3,T4,T5,T6>

A value tuple with 6 components.

Remarks

Create is a helper method that you can call to instantiate a 6-component value tuple without having to explicitly specify the types of its components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)

Creates a new value tuple with 5 components (a quintuple).

C#

```
public static (T1, T2, T3, T4, T5) Create<T1,T2,T3,T4,T5> (T1 item1, T2
item2, T3 item3, T4 item4, T5 item5);
```

Type Parameters

`T1`

The type of the value tuple's first component.

`T2`

The type of the value tuple's second component.

`T3`

The type of the value tuple's third component.

`T4`

The type of the value tuple's fourth component.

`T5`

The type of the value tuple's fifth component.

Parameters

`item1` T1

The value of the value tuple's first component.

`item2` T2

The value of the value tuple's second component.

`item3` T3

The value of the value tuple's third component.

`item4` T4

The value of the value tuple's fourth component.

`item5` T5

The value of the value tuple's fifth component.

Returns

ValueTuple<T1,T2,T3,T4,T5>

A value tuple with 5 components.

Remarks

Create is a helper method that you can call to instantiate a 5-component value tuple without having to explicitly specify the types of its components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2,T3,T4>(T1, T2, T3, T4)

Creates a new value tuple with 4 components (a quadruple).

C#

```
public static (T1, T2, T3, T4) Create<T1,T2,T3,T4> (T1 item1, T2 item2,
T3 item3, T4 item4);
```

Type Parameters

T1

The type of the value tuple's first component.

T2

The type of the value tuple's second component.

T3

The type of the value tuple's third component.

T4

The type of the value tuple's fourth component.

Parameters

`item1` T1

The value of the value tuple's first component.

`item2` T2

The value of the value tuple's second component.

`item3` T3

The value of the value tuple's third component.

`item4` T4

The value of the value tuple's fourth component.

Returns

ValueTuple<T1,T2,T3,T4>

A value tuple with 4 components.

Remarks

Create is a helper method that you can call to instantiate an 4-component value tuple without having to explicitly specify the types of its components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2,T3>(T1, T2, T3)

Creates a new value tuple with 3 components (a triple).

```
C#
```

```
public static (T1, T2, T3) Create<T1,T2,T3> (T1 item1, T2 item2, T3
item3);
```

Type Parameters

`T1`

The type of the value tuple's first component.

`T2`

The type of the value tuple's second component.

`T3`

The type of the value tuple's third component.

Parameters

`item1` T1

The value of the value tuple's first component.

`item2` T2

The value of the value tuple's second component.

`item3` T3

The value of the value tuple's third component.

Returns

ValueTuple<T1,T2,T3>

A value tuple with 3 components.

Remarks

Create is a helper method that you can call to instantiate an 3-component value tuple without having to explicitly specify the types of its components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1,T2>(T1, T2)

Creates a new value tuple with 2 components (a pair).

```
C#
public static (T1, T2) Create<T1,T2> (T1 item1, T2 item2);
```

Type Parameters

`T1`

The type of the value tuple's first component.

`T2`

The type of the value tuple's second component.

Parameters

`item1` T1

The value of the value tuple's first component.

`item2` T2

The value of the value tuple's second component.

Returns

ValueTuple<T1,T2>

A value tuple with 2 components.

Remarks

Create is a helper method that you can call to instantiate an 2-component value tuple without having to explicitly specify the types of its components.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Create<T1>(T1)

Creates a new value tuple with 1 component (a singleton).

C#

```
public static (T1) Create<T1> (T1 item1);
```

Type Parameters

`T1`

The type of the value tuple's only component.

Parameters

`item1` T1

The value of the value tuple's only component.

Returns

ValueTuple<T1>

A value tuple with 1 component.

Remarks

Create is a helper method that you can call to instantiate a 1-component value tuple without having to explicitly specify the type of its component.

Applies to

▼ .NET 9 and other versions

Product	Versions

ValueTuple.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple instance is equal to the specified object.

Overloads

Expand table

Equals(ValueTuple)	Determines whether two ValueTuple instances are equal. This method always returns `true`.
Equals(Object)	Returns a value that indicates whether the current ValueTuple instance is equal to a specified object.

Equals(ValueTuple)

Determines whether two ValueTuple instances are equal. This method always returns `true`.

```
C#

public bool Equals (ValueTuple other);
```

Parameters

`other` ValueTuple

The value tuple to compare with the current instance.

Returns

Boolean

This method always returns `true`.

Implements

Equals(T)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(Object)

Returns a value that indicates whether the current ValueTuple instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare to the current instance.

Returns

Boolean

`true` if `obj` is a ValueTuple instance; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for the current ValueTuple instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

This method always return 0.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the string representation of this ValueTuple instance.

C#

```
public override string ToString ();
```

Returns

String

This method always returns "()".

Remarks

The string returned by this method takes the form `()`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple.IStructuralComparable.CompareTo(Object, IComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple instance to a specified object.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

The object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison. This parameter is ignored.

Returns

Int32

Returns 0 if `other` is a ValueTuple instance and 1 if `other` is `null`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a ValueTuple instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple.IStructuralEquatable.Equals(Object, IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Remarks

This member is an explicit interface implementation. It can only be used when the ValueTuplet> instance is cast to an IStructuralEquatable interface. The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast to a ValueTuple object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple.IStructuralEquatable.GetHashCode(IEqualityComparer) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this ValueTuple instance.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

comparer IEqualityComparer

An object whose GetHashCode(Object) method computes the hash code. This parameter is ignored.

Returns

Int32

The hash code for this ValueTuple instance.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares this ValueTuple instance with a specified object and returns an indication of their relative values.

```
C#

int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

0 if `other` is a ValueTuple instance; otherwise, 1 if `other` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`other` is not a ValueTuple instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns an IndexOutOfRangeException. There are no elements in a `ValueTuple`.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

There is no acceptable value for `index`.

Property Value

Object

An IndexOutOfRangeException.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

There is no acceptable value for `index`.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the length of this `ValueTuple` instance, which is always 0. There are no elements in a `ValueTuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

0, the number of elements in this `ValueTuple` instance.

Implements

Length

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with a single component.

C#

```
public struct ValueTuple<T1> : IComparable, IComparable<(T1)>,
IEquatable<(T1)>, System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's only element.

Inheritance Object → ValueType → ValueTuple<T1>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1>> , IEquatable<ValueTuple<T1>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1>(T1)	Initializes a new ValueTuple<T1> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1> instance's first element.

Methods

Expand table

CompareTo(ValueTuple<T1>)	Compares the current ValueTuple<T1> instance to a specified ValueTuple<T1> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified object.
Equals(ValueTuple<T1>)	Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified ValueTuple<T1> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the `ValueTuple` element.

ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1>(ValueTuple<T1>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>(T1) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1> instance.

C#

```
public ValueTuple (T1 item1);
```

Parameters

`item1` T1

The value tuple's first element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.CompareTo(ValueTuple<T1>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1> instance to a specified ValueTuple<T1> instance.

C#

```
public int CompareTo ((T1) other);
```

Parameters

other ValueTuple<T1>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified object.
Equals(ValueTuple<T1>)	Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified ValueTuple<T1> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1> value type.
- It component is of the same types as that of the current instance.
- Its component is equal to that of the current instance. Equality is determined by the default equality comparer for the component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1>)

Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified ValueTuple<T1> instance.

C#

```
public bool Equals ((T1) other);
```

Parameters

`other` ValueTuple<T1>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1> instance.

Remarks

The string returned by this method takes the form (*Item1*, where *Item1* represents the value of the Item1 field. If the field value is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

The object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the `ValueTuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the `ValueTuple` element. `index` must be 0.

Property Value

Object

The value of the `ValueTuple` element.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 0.

Remarks

The ValueTuple<T1>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1> object to a ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

ValueTuple<T1>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

C#

```
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

1, the number of elements in a ValueTuple<T1> object.

Implements

Length

Remarks

The ValueTuple<T1>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

ValueTuple<T1,T2> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with 2 components.

C#

```
public struct ValueTuple<T1,T2> : IComparable, IComparable<(T1, T2)>,
IEquatable<(T1, T2)>, System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

Inheritance Object → ValueType → ValueTuple<T1,T2>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1,T2>> , IEquatable<ValueTuple<T1,T2>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2>(T1, T2)	Initializes a new ValueTuple<T1,T2> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2> instance's second element.

Methods

Expand table

CompareTo(ValueTuple<T1,T2>)	Compares the current ValueTuple<T1,T2> instance to a specified ValueTuple<T1,T2> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified object.
Equals(ValueTuple<T1,T2>)	Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified ValueTuple<T1,T2> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1,T2> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEquality	Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified object based on a specified

Comparer)	comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1,T2>(ValueTuple<T1,T2>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>(T1, T2) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2> instance.

C#

```
public ValueTuple (T1 item1, T2 item2);
```

Parameters

`item1` T1

The value tuple's first element.

`item2` T2

The value tuple's second element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>.CompareTo(ValueTuple<T1,T2>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2> instance to a specified ValueTuple<T1,T2> instance.

C#

```
public int CompareTo ((T1, T2) other);
```

Parameters

`other` ValueTuple<T1,T2>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified object.
Equals(ValueTuple<T1,T2>)	Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified ValueTuple<T1,T2> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2>)

Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified ValueTuple<T1,T2> instance.

C#

```
public bool Equals ((T1, T2) other);
```

Parameters

`other` ValueTuple<T1,T2>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, where *Item1* and *Item2* represent the values of the Item1 and Item2 fields. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

The object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Remarks

This member is an explicit interface member implementation. It can be used only when the ValueTuple<T1,T2> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals(Object, Object) implementation is called only if `other` is not `null`, and if it can be successfully cast to a ValueTuple<T1,T2> whose components are of the same types as those of the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the ValueTuple<T1,T2> objects to be compared to the Equals(Object, Object) implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two ValueTuple<T1,T2> instances.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

ValueTuple<T1,T2>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.0, 2.1

ValueTuple<T1,T2>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

```
C#
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `ValueTuple` element. `index` can range from 0 to 1.

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 1.

Remarks

The ValueTuple<T1,T2>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2> object to an ITuple interface

object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

2, the number of elements in a ValueTuple<T1,T2> object.

Implements

Length

Remarks

The ValueTuple<T1,T2>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with 3 components.

C#

```
public struct ValueTuple<T1,T2,T3> : IComparable, IComparable<(T1, T2, T3)>,
IEquatable<(T1, T2, T3)>, System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

T3

The type of the value tuple's third element.

Inheritance Object → ValueType → ValueTuple<T1,T2,T3>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1,T2,T3>> , IEquatable<ValueTuple<T1,T2,T3>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2,T3>(T1, T2, T3)	Initializes a new ValueTuple<T1,T2,T3> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2,T3> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2,T3> instance's second element.
Item3	Gets the value of the current ValueTuple<T1,T2,T3> instance's third element.

Methods

Expand table

CompareTo(ValueTuple<T1,T2,T3>)	Compares the current ValueTuple<T1,T2,T3> instance to a specified ValueTuple<T1,T2,T3> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified ValueTuple<T1,T2,T3> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2,T3> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2,T3> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2,T3> instance to a specified object by using a specified comparer and returns an integer that

	indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1,T2,T3> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2,T3> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1,T2,T3>(ValueTuple<T1,T2,T3>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>(T1, T2, T3) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2,T3> instance.

C#

```
public ValueTuple (T1 item1, T2 item2, T3 item3);
```

Parameters

item1 T1

The value tuple's first element.

item2 T2

The value tuple's second element.

item3 T3

The value tuple's third element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>.Item3 Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current ValueTuple<T1,T2,T3> instance's third element.

C#

```
public T3 Item3;
```

Field Value

T3

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>.CompareTo(ValueTuple<T1,T2,T3>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3> instance to a specified ValueTuple<T1,T2,T3> instance.

C#

```
public int CompareTo ((T1, T2, T3) other);
```

Parameters

`other` ValueTuple<T1,T2,T3>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified ValueTuple<T1,T2,T3> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2,T3> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2,T3>)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified ValueTuple<T1,T2,T3> instance.

C#

```
public bool Equals ((T1, T2, T3) other);
```

Parameters

`other` ValueTuple<T1,T2,T3>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2,T3> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2,T3> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2,T3> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, where *Item1*, *Item2*, and *Item3* represent the values of the Item1, Item2, and Item3 fields. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

`other` Object

The object to compare with the current instance.

`comparer` IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2,T3> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `ValueTuple` element. `index` can range from 0 to 2.

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 2.

Remarks

The ValueTuple<T1,T2,T3>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3> object to an ITuple

interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

3, the number of elements in a ValueTuple<T1,T2,T3> object.

Implements

Length

Remarks

The ValueTuple<T1,T2,T3>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3,T4> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with 4 components.

C#

```
public struct ValueTuple<T1,T2,T3,T4> : IComparable, IComparable<(T1, T2,
T3, T4)>, IEquatable<(T1, T2, T3, T4)>,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

T3

The type of the value tuple's third element.

T4

The type of the value tuple's fourth element.

Inheritance Object → ValueType → ValueTuple<T1,T2,T3,T4>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1,T2,T3,T4>> , IEquatable<ValueTuple<T1,T2,T3,T4>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2,T3,T4>(T1, T2, T3, T4)	Initializes a new ValueTuple<T1,T2,T3,T4> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2,T3,T4> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2,T3,T4> instance's second element.
Item3	Gets the value of the current ValueTuple<T1,T2,T3,T4> instance's third element.
Item4	Gets the value of the current ValueTuple<T1,T2,T3,T4> instance's fourth element.

Methods

Expand table

CompareTo(ValueTuple<T1,T2,T3,T4>)	Compares the current ValueTuple<T1,T2,T3,T4> instance to a specified ValueTuple<T1,T2,T3,T4> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified ValueTuple<T1,T2,T3,T4> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2,T3,T4> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1,T2,T3,T4> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1,T2,T3,T4>(ValueTuple<T1,T2,T3,T4>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4>(T1, T2, T3, T4) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2,T3,T4> instance.

C#

```
public ValueTuple (T1 item1, T2 item2, T3 item3, T4 item4);
```

Parameters

item1 T1

The value tuple's first element.

item2 T2

The value tuple's second element.

item3 T3

The value tuple's third element.

item4 T4

The value tuple's fourth element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4>.CompareTo(ValueTuple<T1,T2,T3,T4>) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4> instance to a specified ValueTuple<T1,T2,T3,T4> instance.

C#

```
public int CompareTo ((T1, T2, T3, T4) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3,T4>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified ValueTuple<T1,T2,T3,T4> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2,T3,T4> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2,T3,T4>)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified ValueTuple<T1,T2,T3,T4> instance.

C#

```
public bool Equals ((T1, T2, T3, T4) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3,T4>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2,T3,T4> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3,T4>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2,T3,T4> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, where *Item1*, *Item2*, *Item3*, and *Item4* represent the values of the Item1, Item2, Item3, and Item4 fields. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

The object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2,T3,T4> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `ValueTuple` element. `index` can range from 0 to 3.

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 3.

Remarks

The ValueTuple<T1,T2,T3,T4>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4> object

to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

ValueTuple<T1,T2,T3,T4>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

4, the number of elements in a ValueTuple<T1,T2,T3,T4> object.

Implements

Length

Remarks

The ValueTuple<T1,T2,T3,T4>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3,T4,T5> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with 5 components.

C#

```
public struct ValueTuple<T1,T2,T3,T4,T5> : IComparable, IComparable<(T1, T2,
T3, T4, T5)>, IEquatable<(T1, T2, T3, T4, T5)>,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

T3

The type of the value tuple's third element.

T4

The type of the value tuple's fourth element.

T5

The type of the value tuple's fifth element.

Inheritance Object → ValueType → ValueTuple<T1,T2,T3,T4,T5>

Implements IStructuralComparable , IStructuralEquatable , IComparable ,
IComparable<ValueTuple<T1,T2,T3,T4,T5>> ,

IEquatable<ValueTuple<T1,T2,T3,T4,T5>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5)	Initializes a new ValueTuple<T1,T2,T3,T4,T5> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5> instance's second element.
Item3	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5> instance's third element.
Item4	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5> instance's fourth element.
Item5	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5> instance's fifth element.

Methods

Expand table

CompareTo(ValueTuple<T1,T2,T3,T4,T5>)	Compares the current ValueTuple<T1,T2,T3,T4,T5> instance to a specified ValueTuple<T1,T2,T3,T4,T5> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5> instance.

GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2,T3,T4,T5> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1,T2,T3,T4,T5> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1,T2,T3,T4,T5>(ValueTuple<T1,T2,T3,T4,T5>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5>(T1, T2, T3, T4, T5) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2,T3,T4,T5> instance.

C#

```
public ValueTuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5);
```

Parameters

item1 T1

The value tuple's first element.

item2 T2

The value tuple's second element.

item3 T3

The value tuple's third element.

item4 T4

The value tuple's fourth element.

item5 T5

The value tuple's fifth element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5>.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5> instance to a specified ValueTuple<T1,T2,T3,T4,T5> instance.

C#

```
public int CompareTo ((T1, T2, T3, T4, T5) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4,T5>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2,T3,T4,T5> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2,T3,T4,T5>)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5> instance.

C#

```
public bool Equals ((T1, T2, T3, T4, T5) other);
```

Parameters

other ValueTuple<T1,T2,T3,T4,T5>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions

ValueTuple<T1,T2,T3,T4,T5>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2,T3,T4,T5> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3,T4,T5>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2,T3,T4,T5> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, *Item5*, where *Item1*, *Item2*, *Item3*, *Item4*, and *Item5* represent the values of the Item1, Item2, Item3, Item4, and Item5 fields. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

The object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.

Value	Description
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2,T3,T4,T5> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

Value Tuple<T1,T2,T3,T4,T5>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `ValueTuple` element. `index` can range from 0 to 4.

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 4.

Remarks

The ValueTuple<T1,T2,T3,T4,T5>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5>

object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3,T4,T5>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

5, the number of elements in a ValueTuple<T1,T2,T3,T4,T5> object.

Implements

Length

Remarks

The ValueTuple<T1,T2,T3,T4,T5>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3,T4,T5,T6> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with 6 components.

C#

```
public struct ValueTuple<T1,T2,T3,T4,T5,T6> : IComparable, IComparable<(T1,
T2, T3, T4, T5, T6)>, IEquatable<(T1, T2, T3, T4, T5, T6)>,
System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

T3

The type of the value tuple's third element.

T4

The type of the value tuple's fourth element.

T5

The type of the value tuple's fifth element.

T6

The type of the value tuple's sixth element.

Inheritance Object → ValueType → ValueTuple<T1,T2,T3,T4,T5,T6>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1,T2,T3,T4,T5,T6>> , IEquatable<ValueTuple<T1,T2,T3,T4,T5,T6>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6)	Initializes a new ValueTuple<T1,T2,T3,T4,T5,T6> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance's second element.
Item3	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance's third element.
Item4	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance's fourth element.
Item5	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance's fifth element.
Item6	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance's sixth element.

Methods

Expand table

CompareTo(ValueTuple<T1,T2,T3,T4,T5,T6>)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6> instance to a specified ValueTuple<T1,T2,T3,T4,T5,T6> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified object.

Equals(ValueTuple<T1,T2,T3,T4,T5,T6>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5,T6> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1,T2,T3,T4,T5,T6>(ValueTuple<T1,T2,T3,T4,T5,T6>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5,T6>(T1, T2, T3, T4, T5, T6) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2,T3,T4,T5,T6> instance.

C#

```
public ValueTuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6
item6);
```

Parameters

item1 T1

The value tuple's first element.

item2 T2

The value tuple's second element.

item3 T3

The value tuple's third element.

item4 T4

The value tuple's fourth element.

item5 T5

The value tuple's fifth element.

item6 T6

The value tuple's sixth element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6>.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6> instance to a specified ValueTuple<T1,T2,T3,T4,T5,T6> instance.

C#

```
public int CompareTo ((T1, T2, T3, T4, T5, T6) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4,T5,T6>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5,T6>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5,T6>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2,T3,T4,T5,T6> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2,T3,T4,T5,T6>)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6> instance.

C#

```
public bool Equals ((T1, T2, T3, T4, T5, T6) other);
```

Parameters

other ValueTuple<T1,T2,T3,T4,T5,T6>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5,T6> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2,T3,T4,T5,T6> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, where *Item1*, *Item2*, *Item3*, *Item4*, *Item5*, and *Item6* represent the values of the Item1, Item2, Item3, Item4, Item5, and Item6 fields. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6>.IStructural Comparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

The object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.

Value	Description
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Value Tuple<T1,T2,T3,T4,T5,T6>.IStructural Equatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2,T3,T4,T5,T6> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions

Value Tuple<T1,T2,T3,T4,T5,T6>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `ValueTuple` element. `index` can range from 0 to 5.

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 5.

Remarks

The ValueTuple<T1,T2,T3,T4,T5,T6>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5,T6>

object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

ValueTuple<T1,T2,T3,T4,T5,T6>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

```
C#
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

6, the number of elements in a ValueTuple<T1,T2,T3,T4,T5,T6> object.

Implements

Length

Remarks

The ValueTuple<T1,T2,T3,T4,T5,T6>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5,T6> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

Product	Versions
.NET Standard	2.1

ValueTuple<T1,T2,T3,T4,T5,T6,T7> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a value tuple with 7 components.

C#

```
public struct ValueTuple<T1,T2,T3,T4,T5,T6,T7> : IComparable,
IComparable<(T1, T2, T3, T4, T5, T6, T7)>, IEquatable<(T1, T2, T3, T4, T5,
T6, T7)>, System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

T3

The type of the value tuple's third element.

T4

The type of the value tuple's fourth element.

T5

The type of the value tuple's fifth element.

T6

The type of the value tuple's sixth element.

T7

The type of the value tuple's seventh element.

Inheritance Object → ValueType → ValueTuple<T1,T2,T3,T4,T5,T6,T7>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1,T2,T3,T4,T5,T6,T7>> , IEquatable<ValueTuple<T1,T2,T3,T4,T5,T6,T7>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7)	Initializes a new ValueTuple<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's second element.
Item3	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's third element.
Item4	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's fourth element.
Item5	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's fifth element.
Item6	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's sixth element.
Item7	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's seventh element.

Methods

Expand table

CompareTo(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object, IComparer)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Extension Methods

Expand table

ToTuple<T1,T2,T3,T4,T5,T6,T7>(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)	Converts an instance of the `ValueTuple` structure to an instance of the `Tuple` class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2,T3,T4,T5,T6,T7>(T1, T2, T3, T4, T5, T6, T7) instance.

C#

```
public ValueTuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6
item6, T7 item7);
```

Parameters

item1 T1

The value tuple's first element.

item2 T2

The value tuple's second element.

item3 T3

The value tuple's third element.

item4 T4

The value tuple's fourth element.

item5 T5

The value tuple's fifth element.

item6 T6

The value tuple's sixth element.

item7 T7

The value tuple's seventh element.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6,T7>.Item5 Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's fifth element.

C#

```
public T5 Item5;
```

Field Value

T5

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6,T7>.Item6 Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's sixth element.

C#

```
public T6 Item6;
```

Field Value

T6

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

ValueTuple<T1,T2,T3,T4,T5,T6,T7>.Item7 Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance's seventh element.

C#

```
public T7 Item7;
```

Field Value

T7

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

C#

```
public int CompareTo ((T1, T2, T3, T4, T5, T6, T7) other);
```

Parameters

other ValueTuple<T1,T2,T3,T4,T5,T6,T7>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2,T3,T4,T5,T6,T7> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2,T3,T4,T5,T6,T7>)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

C#

```
public bool Equals ((T1, T2, T3, T4, T5, T6, T7) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4,T5,T6,T7>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3,T4,T5,T6,T7>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

ValueTuple<T1,T2,T3,T4,T5,T6,T7>.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, *Item7*, where *Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, and *Item7* represent the values of the Item1, Item2, Item3, Item4, Item5, Item6, and Item7 fields. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.IStructural Comparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

The object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.

Value	Description
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.IStructural Equatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

other Object

The object to compare with this instance.

comparer IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.IStructural Equatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.IComparable.CompareTo(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

The object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Applies to

Product	Versions

ValueTuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#
object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The index of the specified `ValueTuple` element. `index` can range from 0 (the index of Item1) to 6 (the index of Item7).

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0 or greater than 6.

Remarks

The ValueTuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5,T6,T7> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Collaborate with us on GitHub

Value Tuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

C#

```
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

7, the number of elements in a ValueTuple<T1,T2,T3,T4,T5,T6,T7> object.

Implements

Length

Remarks

The ValueTuple<T1,T2,T3,T4,T5,T6,T7>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5,T6,T7> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Collaborate with us on GitHub

ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents an *n*-value tuple, where *n* is 8 or greater.

C#

```
public struct ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> : IComparable,
IComparable<(T1, T2, T3, T4, T5, T6, T7, TRest)>, IEquatable<(T1, T2, T3,
T4, T5, T6, T7, TRest)>, System.Collections.IStructuralComparable,
System.Collections.IStructuralEquatable,
System.Runtime.CompilerServices.ITuple where TRest : struct
```

Type Parameters

T1

The type of the value tuple's first element.

T2

The type of the value tuple's second element.

T3

The type of the value tuple's third element.

T4

The type of the value tuple's fourth element.

T5

The type of the value tuple's fifth element.

T6

The type of the value tuple's sixth element.

`T7`

The type of the value tuple's seventh element.

`TRest`

Any generic value tuple instance that defines the types of the tuple's remaining elements.

Inheritance Object → ValueType → ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>

Implements IStructuralComparable , IStructuralEquatable , IComparable , IComparable<ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>> , IEquatable<ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>> , ITuple

Remarks

For more information about this API, see Value tuples.

Constructors

Expand table

ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>(T1, T2, T3, T4, T5, T6, T7, TRest)	Initializes a new ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Fields

Expand table

Item1	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's first element.
Item2	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's second element.
Item3	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's third element.
Item4	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's fourth element.

Item5	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's fifth element.
Item6	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's sixth element.
Item7	Gets the value of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's seventh element.
Rest	Gets the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's remaining elements.

Methods

Expand table

CompareTo(ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.
Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.
GetHashCode()	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.
ToString()	Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Explicit Interface Implementations

Expand table

IComparable.CompareTo(Object)	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralComparable.CompareTo(Object,	Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance to a specified object by using a specified comparer and

IComparer)	returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.
IStructuralEquatable.Equals(Object, IEqualityComparer)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified object based on a specified comparison method.
IStructuralEquatable.GetHashCode(IEqualityComparer)	Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance by using a specified computation method.
ITuple.Item[Int32]	Gets the value of the specified `ValueTuple` element.
ITuple.Length	Gets the number of elements in the `ValueTuple`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> Constructor

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

C#

```
public ValueTuple (T1 item1, T2 item2, T3 item3, T4 item4, T5 item5, T6
item6, T7 item7, TRest rest);
```

Parameters

item1 T1

The value tuple's first element.

item2 T2

The value tuple's second element.

item3 T3

The value tuple's third element.

item4 T4

The value tuple's fourth element.

item5 T5

The value tuple's fifth element.

item6 T6

The value tuple's sixth element.

item7 T7

The value tuple's seventh element.

`rest` TRest

An instance of any value tuple type that contains the values of the value's tuple's remaining elements.

Exceptions

ArgumentException

`rest` is not a generic value tuple type.

Remarks

In addition to using your language's build-in support for tuples, you can also create a value tuple by calling the static ValueTuple.Create<T1,T2,T3,T4,T5,T6,T7,T8>(T1, T2, T3, T4, T5, T6, T7, T8) method without having to explicitly specify the types of its elements.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Rest Field

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's remaining elements.

```
C#
public TRest Rest;
```

Field Value

TRest

Remarks

The Rest field returns a nested value tuple that allows access to the eighth though *n*th elements of the tuple. Depending on the total number of elements in the tuple, the values of the eighth through fourteenth components can be retrieved from the nested value tuple's `Item1` through `Item7` properties. You can then use the Rest property of a nested ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to retrieve the value tuple at the next level of nesting.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

C#

```
public int CompareTo ((T1, T2, T3, T4, T5, T6, T7, TRest) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>

The tuple to compare with this instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(T)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified object.

Overloads

Expand table

Equals(Object)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified object.
Equals(ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>)	Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Equals(Object)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

`obj` Object

The object to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified object; otherwise, `false`.

Remarks

The `obj` argument is considered to be equal to the current instance under the following conditions:

- It is a ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> value type.
- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Equals(ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>)

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

```
C#
```

```
public bool Equals ((T1, T2, T3, T4, T5, T6, T7, TRest) other);
```

Parameters

`other` ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>

The value tuple to compare with this instance.

Returns

Boolean

`true` if the current instance is equal to the specified tuple; otherwise, `false`.

Implements

Equals(T)

Remarks

The `other` argument is considered to be equal to the current instance under the following conditions:

- Its components are of the same types as those of the current instance.
- Its components are equal to those of the current instance. Equality is determined by the default equality comparer for each component.

Applies to

▼ .NET 9 and other versions

Product	Versions

ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

The hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.To String Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a string that represents the value of this ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

C#

```
public override string ToString ();
```

Returns

String

The string representation of this ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Remarks

The string returned by this method takes the form (*Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, *Item7*, *Item8*...), where *Item1*, *Item2*, *Item3*, *Item4*, *Item5*, *Item6*, and *Item7* represent the values of the Item1, Item2, Item3, Item4, Item5, Item6, and Item7 fields. *Item8* represents the value of the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance's `Next.Item1` field. The value of any additional nested elements follows *Item8*. If any of the field values is `null`, it is represented as String.Empty.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IStructuralComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance to a specified object by using a specified comparer and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IStructuralComparable.CompareTo (object other,
System.Collections.IComparer comparer);
```

Parameters

other Object

The object to compare with the current instance.

comparer IComparer

An object that provides custom rules for comparison.

Returns

Int32

A signed integer that indicates the relative position of this instance and `other` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object, IComparer)

Exceptions

ArgumentException

`other` is not a ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Remarks

This member is an explicit interface implementation. It can only be used when the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IStructuralComparable interface.

This method lets you define customized comparisons of ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects. For example, you can use this method to order ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects based on the value of a specific component.

Although this method can be called directly, it is most commonly called by collection-sorting methods that include IComparer parameters to order the members of a collection. For example, it is called by the Array.Sort(Array, IComparer) method and the Add method of a SortedList object that is instantiated by using the SortedList.SortedList(IComparer) constructor.

> ⊗ **Caution**
>
> The **IStructuralComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **IStructuralEquatable.Equals** method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Collaborate with us on GitHub

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IStructuralEquatable.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value that indicates whether the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is equal to a specified object based on a specified comparison method.

C#

```
bool IStructuralEquatable.Equals (object other,
System.Collections.IEqualityComparer comparer);
```

Parameters

`other` Object

The object to compare with this instance.

`comparer` IEqualityComparer

An object that defines the method to use to evaluate whether the two objects are equal.

Returns

Boolean

`true` if the current instance is equal to the specified objects; otherwise, `false`.

Implements

Equals(Object, IEqualityComparer)

Remarks

This member is an explicit interface implementation. It can only be used when the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IStructuralEquatable interface.

The IEqualityComparer.Equals implementation is called only if `other` is not `null`, and if it can be successfully cast to a ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object that has the same total number of components (including those in nested tuple objects) of the same types as the current instance. The IStructuralEquatable.Equals(Object, IEqualityComparer) method first passes the Item1 values of the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects to be compared to the IEqualityComparer.Equals implementation. If this method call returns `true`, the method is called again and passed the Item2 values of the two ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects. This continues until the method call returns `false` when it compares a specific pair of values, or the two Rest values are passed to the method.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IStructuralEquatable.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Calculates the hash code for the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance by using a specified computation method.

C#

```
int IStructuralEquatable.GetHashCode (System.Collections.IEqualityComparer comparer);
```

Parameters

`comparer` IEqualityComparer

An object whose GetHashCode(Object) method calculates the hash code of the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance.

Returns

Int32

A 32-bit signed integer hash code.

Implements

GetHashCode(IEqualityComparer)

Remarks

This member is an explicit interface implementation. It can only be used when the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IStructuralEquatable

interface. The method simply wraps a call to the `comparer` object's IEqualityComparer.GetHashCode implementation.

The algorithm used to compute the hash code should return the same hash code for two ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> objects that are considered to be equal.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IComparable.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to a specified object and returns an integer that indicates whether the current object is before, after, or in the same position as the specified object in the sort order.

C#

```
int IComparable.CompareTo (object other);
```

Parameters

`other` Object

An object to compare with the current instance.

Returns

Int32

A signed integer that indicates the relative position of this instance and `obj` in the sort order, as shown in the following table.

Expand table

Value	Description
A negative integer	This instance precedes `other`.
Zero	This instance and `other` have the same position in the sort order.
A positive integer	This instance follows `other`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`other` is not a ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object.

Remarks

This member is an explicit interface member implementation. It can be used only when the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> instance is cast to an IComparable interface.

This method provides the IComparable.CompareTo implementation for the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> structure. Although the method can be called directly, it is most commonly called by the default overloads of collection-sorting methods, such as Array.Sort(Array) and SortedList.Add, to order the members of a collection.

> **⊗ Caution**
>
> The **ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.IComparable.CompareTo** method is intended for use in sorting operations. It should not be used when the primary purpose of a comparison is to determine whether two objects are equal. To determine whether two objects are equal, call the **ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.Equals(Object)** method.

This method uses the default object comparer to compare each component.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Item[Int32] Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the specified `ValueTuple` element.

```
C#

object? System.Runtime.CompilerServices.ITuple.Item[int index] { get; }
```

Parameters

`index` Int32

The value of the specified `ValueTuple` element. `index` can range from 0 for `Item1` to one less than the number of elements in the `ValueTuple`.

Property Value

Object

The value of the `ValueTuple` element at the specified position.

Implements

Item[Int32]

Exceptions

IndexOutOfRangeException

`index` is less than 0.

-or-

`index` is greater than or equal to ITuple.Length.

Remarks

The ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Item[] property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.1

Value Tuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Length Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the number of elements in the `ValueTuple`.

C#

```
int System.Runtime.CompilerServices.ITuple.Length { get; }
```

Property Value

Int32

The number of elements in the `ValueTuple`.

Implements

Length

Remarks

The ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest>.ITuple.Length property is an explicit interface implementation. To call it, you must cast or convert the ValueTuple<T1,T2,T3,T4,T5,T6,T7,TRest> object to an ITuple interface object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	4.7.1, 4.7.2, 4.8, 4.8.1

ValueType Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Provides the base class for value types.

```
C#
public abstract class ValueType
```

Inheritance Object → ValueType

Derived _GUID
Accessibility.__MIDL_IWinTypes_0009
Accessibility._RemotableHandle
IStream
ISymUnmanagedBinder
More...

Remarks

ValueType overrides the virtual methods from Object with more appropriate implementations for value types. See also Enum, which inherits from ValueType.

Data types are separated into value types and reference types. Value types are either stack-allocated or allocated inline in a structure. Reference types are heap-allocated. Both reference and value types are derived from the ultimate base class Object. In cases where it is necessary for a value type to behave like an object, a wrapper that makes the value type look like a reference object is allocated on the heap, and the value type's value is copied into it. The wrapper is marked so the system knows that it contains a value type. This process is known as boxing, and the reverse process is known as unboxing. Boxing and unboxing allow any type to be treated as an object.

Although ValueType is the implicit base class for value types, you cannot create a class that inherits from ValueType directly. Instead, individual compilers provide a language

keyword or construct (such as `struct` in C# and `Structure`...`End Structure` in Visual Basic) to support the creation of value types.

Aside from serving as the base class for value types in the .NET Framework, the ValueType structure is generally not used directly in code. However, it can be used as a parameter in method calls to restrict possible arguments to value types instead of all objects, or to permit a method to handle a number of different value types. The following example illustrates how ValueType prevents reference types from being passed to methods. It defines a class named `Utility` that contains four methods: `IsNumeric`, which indicates whether its argument is a number; `IsInteger`, which indicates whether its argument is an integer; `IsFloat`, which indicates whether its argument is a floating-point number; and `Compare`, which indicates the relationship between two numeric values. In each case, the method parameters are of type ValueType, and reference types are prevented from being passed to the methods.

C#

```
using System;
using System.Numerics;

public class Utility
{
   public enum NumericRelationship {
      GreaterThan = 1,
      EqualTo = 0,
      LessThan = -1
   };

   public static NumericRelationship Compare(ValueType value1, ValueType
value2)
   {
      if (! IsNumeric(value1))
         throw new ArgumentException("value1 is not a number.");
      else if (! IsNumeric(value2))
         throw new ArgumentException("value2 is not a number.");

      // Use BigInteger as common integral type
      if (IsInteger(value1) && IsInteger(value2)) {
         BigInteger bigint1 = (BigInteger) value1;
         BigInteger bigint2 = (BigInteger) value2;
         return (NumericRelationship) BigInteger.Compare(bigint1, bigint2);
      }
      // At least one value is floating point; use Double.
      else {
         Double dbl1 = 0;
         Double dbl2 = 0;
         try {
            dbl1 = Convert.ToDouble(value1);
         }
```

```
            catch (OverflowException) {
               Console.WriteLine("value1 is outside the range of a Double.");
            }
            try {
               dbl2 = Convert.ToDouble(value2);
            }
            catch (OverflowException) {
               Console.WriteLine("value2 is outside the range of a Double.");
            }
            return (NumericRelationship) dbl1.CompareTo(dbl2);
         }
      }

      public static bool IsInteger(ValueType value)
      {
         return (value is SByte || value is Int16 || value is Int32
                 || value is Int64 || value is Byte || value is UInt16
                 || value is UInt32 || value is UInt64
                 || value is BigInteger);
      }

      public static bool IsFloat(ValueType value)
      {
         return (value is float | value is double | value is Decimal);
      }

      public static bool IsNumeric(ValueType value)
      {
         return (value is Byte ||
                 value is Int16 ||
                 value is Int32 ||
                 value is Int64 ||
                 value is SByte ||
                 value is UInt16 ||
                 value is UInt32 ||
                 value is UInt64 ||
                 value is BigInteger ||
                 value is Decimal ||
                 value is Double ||
                 value is Single);
      }
   }
```

The following example illustrates calls to the methods of the `Utility` class.

C#

```
public class Example
{
   public static void Main()
   {
      Console.WriteLine(Utility.IsNumeric(12));
      Console.WriteLine(Utility.IsNumeric(true));
```

```
        Console.WriteLine(Utility.IsNumeric('c'));
        Console.WriteLine(Utility.IsNumeric(new DateTime(2012, 1, 1)));
        Console.WriteLine(Utility.IsInteger(12.2));
        Console.WriteLine(Utility.IsInteger(123456789));
        Console.WriteLine(Utility.IsFloat(true));
        Console.WriteLine(Utility.IsFloat(12.2));
        Console.WriteLine(Utility.IsFloat(12));
        Console.WriteLine("{0} {1} {2}", 12.1, Utility.Compare(12.1, 12), 12);
    }
}
// The example displays the following output:
//       True
//       False
//       False
//       False
//       False
//       True
//       False
//       True
//       False
//       12.1 GreaterThan 12
```

Constructors

Expand table

ValueType()	Initializes a new instance of the ValueType class.

Methods

Expand table

Equals(Object)	Indicates whether this instance and a specified object are equal.
GetHashCode()	Returns the hash code for this instance.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns the fully qualified type name of this instance.

Applies to

ValueType.Equals(Object) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Indicates whether this instance and a specified object are equal.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

The object to compare with the current instance.

Returns

Boolean

`true` if `obj` and this instance are the same type and represent the same value; otherwise, `false`.

Examples

The following example demonstrates how the Equals method can be overridden by a derived value type.

C#

```
public struct Complex
{
    public double m_Re;
    public double m_Im;

    public override bool Equals( object ob ){
        if( ob is Complex ) {
            Complex c = (Complex) ob;
            return m_Re==c.m_Re && m_Im==c.m_Im;
```

```
        }
        else {
            return false;
        }
    }

    public override int GetHashCode(){
        return m_Re.GetHashCode() ^ m_Im.GetHashCode();
    }
}
```

Remarks

The ValueType.Equals(Object) method overrides Object.Equals(Object) and provides the default implementation of value equality for all value types in .NET.

The default implementation calls Object.Equals(Object) on each field of the current instance and `obj` and returns `true` if all fields are equal.

> **Tip**
>
> Particularly if your value type contains fields that are reference types, you should override the **Equals(Object)** method. This can improve performance and enable you to more closely represent the meaning of equality for the type.

Notes for the Windows Runtime

When you call the Equals method on a Windows Runtime structure, it provides the default behavior for value types that don't override Equals. This is part of the support that .NET provides for the Windows Runtime (see .NET Support for Windows Store Apps and Windows Runtime). Windows Runtime structures can't override Equals, even if they're written with C# or Visual Basic, because they can't have methods. (In addition, structures in the Windows Runtime itself don't inherit ValueType.) However, they appear to have ToString, Equals, and GetHashCode methods when you use them in your C# or Visual Basic code, and .NET provides the default behavior for these methods.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ValueType.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the hash code for this instance.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer that is the hash code for this instance.

Examples

The following example demonstrates how the GetHashCode method can be overridden by a derived value type.

C#

```
public struct Complex
{
    public double m_Re;
    public double m_Im;

    public override bool Equals( object ob ){
        if( ob is Complex ) {
            Complex c = (Complex) ob;
            return m_Re==c.m_Re && m_Im==c.m_Im;
        }
        else {
            return false;
        }
    }

    public override int GetHashCode(){
        return m_Re.GetHashCode() ^ m_Im.GetHashCode();
```

```
    }
}
```

Remarks

The GetHashCode method applies to types derived from ValueType. One or more fields of the derived type is used to calculate the return value. If you call the derived type's `GetHashCode` method, the return value is not likely to be suitable for use as a key in a hash table. Additionally, if the value of one or more of those fields changes, the return value might become unsuitable for use as a key in a hash table. In either case, consider writing your own implementation of the GetHashCode method that more closely represents the concept of a hash code for the type.

For more information, see Object.GetHashCode, and System.Collections.Hashtable.

Notes for the Windows Runtime

When you call the GetHashCode method on a Windows Runtime structure, it provides the default behavior for value types that don't override GetHashCode. This is part of the support that .NET provides for the Windows Runtime (see .NET Support for Windows Store Apps and Windows Runtime). Windows Runtime structures can't override GetHashCode, even if they're written with C# or Visual Basic, because they can't have methods. (In addition, structures in the Windows Runtime itself don't inherit ValueType.) However, they appear to have ToString, Equals, and GetHashCode methods when you use them in your C# or Visual Basic code, and .NET provides the default behavior for these methods.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ValueType.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns the fully qualified type name of this instance.

C#

```
public override string? ToString ();
```

Returns

String

The fully qualified type name.

Remarks

The ValueType.ToString method overrides the Object.ToString method and provides the default implementation of the `ToString` method for value types. (Value types are types defined by the `struct` keyword in C#, and by the `Structure`...`End Structure` construct in Visual Basic.) Functionally, however, the implementation is that same as that of Object.ToString: the method returns the fully qualified type name.

Value types defined by the `struct` keyword in C# and the `Structure`...`End Structure` construct in Visual Basic typically override the ValueType.ToString method to provide a more meaningful string representation of the value type. The following example illustrates the difference. It defines two value types, `EmployeeA` and `EmployeeB`, creates an instance of each, and calls its `ToString` method. Because the `EmployeeA` structure does not override the ValueType.ToString method, it displays only the fully qualified type name. The `EmployeeB.ToString` method, on the other hand, provides meaningful information about the object.

C#

```
using System;
using Corporate.EmployeeObjects;

public class Example
{
   public static void Main()
   {
      var empA = new EmployeeA{ Name = "Robert",};
      Console.WriteLine(empA.ToString());

      var empB = new EmployeeB{ Name = "Robert",};
      Console.WriteLine(empB.ToString());
   }
}

namespace Corporate.EmployeeObjects
{
    public struct EmployeeA
    {
         public String Name { get; set; }
    }

    public struct EmployeeB
    {
         public String Name { get; set; }

         public override String ToString()
         {
              return Name;
         }
    }
}
// The example displays the following output:
//     Corporate.EmployeeObjects.EmployeeA
//     Robert
```

Note that, although enumeration types are also value types, they derive from the Enum class, which overrides ValueType.ToString.

Notes for the Windows Runtime

When you call the ToString method on a Windows Runtime structure, it provides the default behavior for value types that don't override ToString. This is part of the support that .NET provides for the Windows Runtime (see .NET Support for Windows Store Apps and Windows Runtime). Windows Runtime structures can't override ToString, even if they're written with C# or Visual Basic, because they can't have methods. (In addition, structures in the Windows Runtime itself don't inherit ValueType.) However, they appear

to have ToString, Equals, and GetHashCode methods when you use them in your C# or Visual Basic code, and .NET provides the default behavior for these methods.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents the version number of an assembly, operating system, or the common language runtime. This class cannot be inherited.

```C#
public sealed class Version : ICloneable, IComparable, IComparable<Version>, IEquatable<Version>, ISpanFormattable, IUtf8SpanFormattable
```

Inheritance Object → Version

Implements IComparable , IComparable<Version> , IEquatable<Version> , ICloneable , IFormattable , ISpanFormattable , IUtf8SpanFormattable

Examples

The following example uses the AssemblyVersionAttribute attribute to assign a version number to an assembly. At compile time, this version information is stored with the assembly's metadata. At run time, the example retrieves the value of the Type.Assembly property on a type found in the assembly to get a reference to the executing assembly, and it retrieves the assembly's version information from the Version property of the AssemblyName object returned by the Assembly.GetName method.

```C#
using System;
using System.Reflection;

[assembly:AssemblyVersionAttribute("2.0.1")]

public class Example1
{
   public static void Main()
   {
      Assembly thisAssem = typeof(Example1).Assembly;
```

```
        AssemblyName thisAssemName = thisAssem.GetName();

        Version ver = thisAssemName.Version;

        Console.WriteLine("This is version {0} of {1}.", ver,
thisAssemName.Name);
    }
}
// The example displays the following output:
//         This is version 2.0.1.0 of Example1.
```

Remarks

For more information about this API, see Supplemental API remarks for Version.

Constructors

Expand table

Version()	Initializes a new instance of the Version class.
Version(Int32, Int32)	Initializes a new instance of the Version class using the specified major and minor values.
Version(Int32, Int32, Int32)	Initializes a new instance of the Version class using the specified major, minor, and build values.
Version(Int32, Int32, Int32, Int32)	Initializes a new instance of the Version class with the specified major, minor, build, and revision numbers.
Version(String)	Initializes a new instance of the Version class using the specified string.

Properties

Expand table

Build	Gets the value of the build component of the version number for the current Version object.
Major	Gets the value of the major component of the version number for the current Version object.
Major Revision	Gets the high 16 bits of the revision number.

Minor	Gets the value of the minor component of the version number for the current Version object.
Minor Revision	Gets the low 16 bits of the revision number.
Revision	Gets the value of the revision component of the version number for the current Version object.

Methods

Expand table

Clone()	Returns a new Version object whose value is the same as the current Version object.
CompareTo(Object)	Compares the current Version object to a specified object and returns an indication of their relative values.
CompareTo(Version)	Compares the current Version object to a specified Version object and returns an indication of their relative values.
Equals(Object)	Returns a value indicating whether the current Version object is equal to a specified object.
Equals(Version)	Returns a value indicating whether the current Version object and a specified Version object represent the same value.
GetHashCode()	Returns a hash code for the current Version object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
Parse(ReadOnlySpan<Char>)	Converts the specified read-only span of characters that represents a version number to an equivalent Version object.
Parse(String)	Converts the string representation of a version number to an equivalent Version object.
ToString()	Converts the value of the current Version object to its equivalent String representation.
ToString(Int32)	Converts the value of the current Version object to its equivalent String representation. A specified count indicates the number of components to return.

TryFormat(Span<Byte>, Int32)	Tries to format this version instance into a span of bytes.
TryFormat(Span<Byte>, Int32, Int32)	Tries to format this version instance into a span of bytes.
TryFormat(Span<Char>, Int32)	Tries to format this version instance into a span of characters.
TryFormat(Span<Char>, Int32, Int32)	Tries to format this version instance into a span of characters.
TryParse(ReadOnlySpan<Char>, Version)	Tries to convert the specified read-only span of characters representing a version number to an equivalent Version object, and returns a value that indicates whether the conversion succeeded.
TryParse(String, Version)	Tries to convert the string representation of a version number to an equivalent Version object, and returns a value that indicates whether the conversion succeeded.

Operators

Expand table

Equality(Version, Version)	Determines whether two specified Version objects are equal.
GreaterThan(Version, Version)	Determines whether the first specified Version object is greater than the second specified Version object.
GreaterThanOrEqual(Version, Version)	Determines whether the first specified Version object is greater than or equal to the second specified Version object.
Inequality(Version, Version)	Determines whether two specified Version objects are not equal.
LessThan(Version, Version)	Determines whether the first specified Version object is less than the second specified Version object.
LessThanOrEqual(Version, Version)	Determines whether the first specified Version object is less than or equal to the second Version object.

Explicit Interface Implementations

Expand table

IFormattable.ToString(String, IFormatProvider)	Formats the value of the current instance using the specified format.

ISpanFormattable.TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance into the provided span of characters.
IUtf8SpanFormattable.TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)	Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the Version class with the specified major, minor, build, and revision numbers.

Overloads

Expand table

Version()	Initializes a new instance of the Version class.
Version(String)	Initializes a new instance of the Version class using the specified string.
Version(Int32, Int32)	Initializes a new instance of the Version class using the specified major and minor values.
Version(Int32, Int32, Int32)	Initializes a new instance of the Version class using the specified major, minor, and build values.
Version(Int32, Int32, Int32, Int32)	Initializes a new instance of the Version class with the specified major, minor, build, and revision numbers.

Version()

Initializes a new instance of the Version class.

C#

```
public Version ();
```

Remarks

This constructor creates a Version object with the following property values.

Expand table

Property	Value
Major	0
Minor	0
Build	undefined (-1)
Revision	undefined (-1)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Version(String)

Initializes a new instance of the Version class using the specified string.

C#

```
public Version (string version);
```

Parameters

`version` String

A string containing the major, minor, build, and revision numbers, where each number is delimited with a period character ('.').

Exceptions

ArgumentException

`version` has fewer than two components or more than four components.

ArgumentNullException

`version` is `null`.

ArgumentOutOfRangeException

A major, minor, build, or revision component is less than zero.

FormatException

At least one component of `version` does not parse to an integer.

OverflowException

At least one component of `version` represents a number greater than Int32.MaxValue.

Remarks

The `version` parameter can contain only the components major, minor, build, and revision, in that order, and all separated by periods. There must be at least two components, and at most four. The first two components are assumed to be major and minor. The value of unspecified components is undefined.

The format of the version number is as follows. Optional components are shown in square brackets ('[' and ']'):

major.minor[.build[.revision]]

All defined components must be integers greater than or equal to 0. For example, if the major number is 6, the minor number is 2, the build number is 1, and the revision number is 3, then `version` should be "6.2.1.3".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Version(Int32, Int32)

Initializes a new instance of the Version class using the specified major and minor values.

```
C#
public Version (int major, int minor);
```

Parameters

`major` Int32

The major version number.

`minor` Int32

The minor version number.

Exceptions

ArgumentOutOfRangeException

`major` or `minor` is less than zero.

Remarks

This constructor creates a Version object with the following property values.

Expand table

Property	Value
Major	`major`
Minor	`minor`
Build	undefined (-1)
Revision	undefined (-1)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Version(Int32, Int32, Int32)

Initializes a new instance of the Version class using the specified major, minor, and build values.

C#

```
public Version (int major, int minor, int build);
```

Parameters

`major` Int32

The major version number.

`minor` Int32

The minor version number.

`build` Int32

The build number.

Exceptions

ArgumentOutOfRangeException

`major`, `minor`, or `build` is less than zero.

Remarks

This constructor creates a Version object with the following property values.

Expand table

Property	Value
Major	`major`
Minor	`minor`
Build	`build`
Revision	undefined (-1)

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Version(Int32, Int32, Int32, Int32)

Initializes a new instance of the Version class with the specified major, minor, build, and revision numbers.

C#

```
public Version (int major, int minor, int build, int revision);
```

Parameters

`major` Int32

The major version number.

`minor` Int32

The minor version number.

`build` Int32

The build number.

`revision` Int32

The revision number.

Exceptions

ArgumentOutOfRangeException

`major`, `minor`, `build`, or `revision` is less than zero.

Examples

The following code example demonstrates the Version constructor, and Major, Minor, Build, Revision, MajorRevision, and MinorRevision properties.

C#

```
// This example demonstrates the Version.Revision,
// MajorRevision, and MinorRevision properties.
using System;

class Sample
{
    public static void Main()
    {

    string fmtStd = "Standard version:\n" +
                    "  major.minor.build.revision = {0}.{1}.{2}.{3}";
    string fmtInt = "Interim version:\n" +
                    "  major.minor.build.majRev/minRev = {0}.{1}.{2}.
{3}/{4}";

    Version std = new Version(2, 4, 1128, 2);
    Version interim = new Version(2, 4, 1128, (100 << 16) + 2);

    Console.WriteLine(fmtStd, std.Major, std.Minor, std.Build,
std.Revision);
    Console.WriteLine(fmtInt, interim.Major, interim.Minor,
interim.Build,
                              interim.MajorRevision,
interim.MinorRevision);
    }
}
/*
```

```
This code example produces the following results:

Standard version:
  major.minor.build.revision = 2.4.1128.2
Interim version:
  major.minor.build.majRev/minRev = 2.4.1128.100/2

*/
```

Remarks

This constructor creates a Version object with the following property values.

Expand table

Property	Value
Major	`major`
Minor	`minor`
Build	`build`
Revision	`revision`

Applies to

▼ .NET 9 and other versions

Product	Versions

Version.Build Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the build component of the version number for the current Version object.

C#

```
public int Build { get; }
```

Property Value

Int32

The build number, or -1 if the build number is undefined.

Examples

The following code example demonstrates the Version constructor, and Major, Minor, Build, Revision, MajorRevision, and MinorRevision properties.

C#

```
// This example demonstrates the Version.Revision,
// MajorRevision, and MinorRevision properties.
using System;

class Sample
{
    public static void Main()
    {

    string fmtStd = "Standard version:\n" +
                    "  major.minor.build.revision = {0}.{1}.{2}.{3}";
    string fmtInt = "Interim version:\n" +
                    "  major.minor.build.majRev/minRev = {0}.{1}.{2}.
{3}/{4}";

    Version std = new Version(2, 4, 1128, 2);
```

```
    Version interim = new Version(2, 4, 1128, (100 << 16) + 2);

    Console.WriteLine(fmtStd, std.Major, std.Minor, std.Build,
std.Revision);
    Console.WriteLine(fmtInt, interim.Major, interim.Minor, interim.Build,
                              interim.MajorRevision, interim.MinorRevision);
    }
}
/*
This code example produces the following results:

Standard version:
  major.minor.build.revision = 2.4.1128.2
Interim version:
  major.minor.build.majRev/minRev = 2.4.1128.100/2

*/
```

Remarks

For example, if the version number is 6.2.1.3, the build number is 1. If the version number is 6.2, the build number is undefined.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version.Major Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the major component of the version number for the current Version object.

C#

```
public int Major { get; }
```

Property Value

Int32

The major version number.

Remarks

For example, if the version number is 6.2, the major version is 6.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Version.MajorRevision Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the high 16 bits of the revision number.

C#

```
public short MajorRevision { get; }
```

Property Value

Int16

A 16-bit signed integer.

Examples

The following code example demonstrates the Version constructor, and the Major, Minor, Build, Revision, MajorRevision, and MinorRevision properties.

C#

```
// This example demonstrates the Version.Revision,
// MajorRevision, and MinorRevision properties.
using System;

class Sample
{
    public static void Main()
    {

    string fmtStd = "Standard version:\n" +
                    "  major.minor.build.revision = {0}.{1}.{2}.{3}";
    string fmtInt = "Interim version:\n" +
                    "  major.minor.build.majRev/minRev = {0}.{1}.{2}.
{3}/{4}";

    Version std = new Version(2, 4, 1128, 2);
    Version interim = new Version(2, 4, 1128, (100 << 16) + 2);
```

```
    Console.WriteLine(fmtStd, std.Major, std.Minor, std.Build,
std.Revision);
    Console.WriteLine(fmtInt, interim.Major, interim.Minor, interim.Build,
                              interim.MajorRevision, interim.MinorRevision);
    }
}
/*
This code example produces the following results:

Standard version:
  major.minor.build.revision = 2.4.1128.2
Interim version:
  major.minor.build.majRev/minRev = 2.4.1128.100/2

*/
```

Remarks

Suppose you release an interim version of your application to temporarily correct a problem until you can release a permanent solution. The temporary version does not warrant a new revision number, but it does need to be identified as a different version. In this case, encode the identification information in the high and low 16-bit portions of the 32-bit revision number. Use the Revision property to obtain the entire revision number, use the MajorRevision property to obtain the high 16 bits, and use the MinorRevision property to obtain the low 16 bits.

Starting in the .NET Framework version 2.0, the Windows NT operating system uses the MajorRevision property to encode the service pack number.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Version.Minor Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the minor component of the version number for the current Version object.

C#

```
public int Minor { get; }
```

Property Value

Int32

The minor version number.

Examples

The following code example demonstrates the Version constructor, and Major, Minor, Build, Revision, MajorRevision, and MinorRevision properties.

C#

```
// This example demonstrates the Version.Revision,
// MajorRevision, and MinorRevision properties.
using System;

class Sample
{
    public static void Main()
    {

    string fmtStd = "Standard version:\n" +
                    "  major.minor.build.revision = {0}.{1}.{2}.{3}";
    string fmtInt = "Interim version:\n" +
                    "  major.minor.build.majRev/minRev = {0}.{1}.{2}.
{3}/{4}";

    Version std = new Version(2, 4, 1128, 2);
```

```
    Version interim = new Version(2, 4, 1128, (100 << 16) + 2);

    Console.WriteLine(fmtStd, std.Major, std.Minor, std.Build,
std.Revision);
    Console.WriteLine(fmtInt, interim.Major, interim.Minor, interim.Build,
                              interim.MajorRevision, interim.MinorRevision);
    }
}
/*
This code example produces the following results:

Standard version:
  major.minor.build.revision = 2.4.1128.2
Interim version:
  major.minor.build.majRev/minRev = 2.4.1128.100/2

*/
```

Remarks

For example, if the version number is 6.2, the minor version is 2.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version.Revision Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets the value of the revision component of the version number for the current Version object.

C#

```
public int Revision { get; }
```

Property Value

Int32

The revision number, or -1 if the revision number is undefined.

Examples

The following code example demonstrates the Version constructor, and Major, Minor, Build, Revision, MajorRevision, and MinorRevision properties.

C#

```
// This example demonstrates the Version.Revision,
// MajorRevision, and MinorRevision properties.
using System;

class Sample
{
    public static void Main()
    {

    string fmtStd = "Standard version:\n" +
                    "  major.minor.build.revision = {0}.{1}.{2}.{3}";
    string fmtInt = "Interim version:\n" +
                    "  major.minor.build.majRev/minRev = {0}.{1}.{2}.
{3}/{4}";

    Version std = new Version(2, 4, 1128, 2);
```

```
    Version interim = new Version(2, 4, 1128, (100 << 16) + 2);

    Console.WriteLine(fmtStd, std.Major, std.Minor, std.Build,
std.Revision);
    Console.WriteLine(fmtInt, interim.Major, interim.Minor, interim.Build,
                              interim.MajorRevision, interim.MinorRevision);
    }
}
/*
This code example produces the following results:

Standard version:
  major.minor.build.revision = 2.4.1128.2
Interim version:
  major.minor.build.majRev/minRev = 2.4.1128.100/2

*/
```

Remarks

For example, if the version number is 6.2.1.3, the revision number is 3. If the version number is 6.2, the revision number is undefined.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Version.Clone Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a new Version object whose value is the same as the current Version object.

C#

```
public object Clone ();
```

Returns

Object

A new Object whose values are a copy of the current Version object.

Implements

Clone()

Remarks

If the type of the return value is important, cast the Object instance that is returned by this method to a Version object.

Applies to

Product	Versions
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

Version.CompareTo Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Compares the current Version object to a specified object or Version and returns an indication of their relative values.

Overloads

Expand table

CompareTo(Version)	Compares the current Version object to a specified Version object and returns an indication of their relative values.
CompareTo(Object)	Compares the current Version object to a specified object and returns an indication of their relative values.

CompareTo(Version)

Compares the current Version object to a specified Version object and returns an indication of their relative values.

```
C#

public int CompareTo (Version? value);
```

Parameters

`value` Version

A Version object to compare to the current Version object, or `null`.

Returns

Int32

A signed integer that indicates the relative values of the two objects, as shown in the following table.

Expand table

Return value	Meaning
Less than zero	The current Version object is a version before `value`.
Zero	The current Version object is the same version as `value`.
Greater than zero	The current Version object is a version subsequent to `value`, or `value` is `null`.

Implements

CompareTo(T)

Examples

The following code example demonstrates generic and nongeneric versions of the `CompareTo` method for several value and reference types.

C#

```
// This example demonstrates the generic and non-generic versions of the
// CompareTo method for several base types.
// The non-generic version takes a parameter of type Object, while the
generic
// version takes a type-specific parameter, such as Boolean, Int32, or
Double.

using System;

class Sample
{
    public static void Main()
    {
    string    nl = Environment.NewLine;
    string    msg = "{0}The following is the result of using the generic
and non-generic{0}" +
                    "versions of the CompareTo method for several base
types:{0}";

    DateTime  now = DateTime.Now;
// Time span = 11 days, 22 hours, 33 minutes, 44 seconds
    TimeSpan  tsX = new TimeSpan(11, 22, 33, 44);
// Version = 1.2.333.4
    Version   versX = new Version("1.2.333.4");
```

```
// Guid = CA761232-ED42-11CE-BACD-00AA0057B223
    Guid      guidX = new Guid("{CA761232-ED42-11CE-BACD-00AA0057B223}");

    Boolean  a1 = true,  a2 = true;
    Byte     b1 = 1,     b2 = 1;
    Int16    c1 = -2,    c2 = 2;
    Int32    d1 = 3,     d2 = 3;
    Int64    e1 = 4,     e2 = -4;
    Decimal  f1 = -5.5m, f2 = 5.5m;
    Single   g1 = 6.6f,  g2 = 6.6f;
    Double   h1 = 7.7d,  h2 = -7.7d;
    Char     i1 = 'A',   i2 = 'A';
    String   j1 = "abc", j2 = "abc";
    DateTime k1 = now,   k2 = now;
    TimeSpan l1 = tsX,   l2 = tsX;
    Version  m1 = versX, m2 = new Version("2.0");
    Guid     n1 = guidX, n2 = guidX;

d1.CompareTo((Object)d2));
        Show("Int64:    ", e1, e2, e1.CompareTo(e2),
e1.CompareTo((Object)e2));
        Show("Decimal:  ", f1, f2, f1.CompareTo(f2),
f1.CompareTo((Object)f2));
        Show("Single:   ", g1, g2, g1.CompareTo(g2),
g1.CompareTo((Object)g2));
        Show("Double:   ", h1, h2, h1.CompareTo(h2),
h1.CompareTo((Object)h2));
        Show("Char:     ", i1, i2, i1.CompareTo(i2),
i1.CompareTo((Object)i2));
        Show("String:   ", j1, j2, j1.CompareTo(j2),
j1.CompareTo((Object)j2));
        Show("DateTime: ", k1, k2, k1.CompareTo(k2),
k1.CompareTo((Object)k2));
        Show("TimeSpan: ", l1, l2, l1.CompareTo(l2),
```

```
l1.CompareTo((Object)l2));
        Show("Version:  ", m1, m2, m1.CompareTo(m2),
m1.CompareTo((Object)m2));
        Show("Guid:     ", n1, n2, n1.CompareTo(n2),
n1.CompareTo((Object)n2));
//
        Console.WriteLine("{0}The following types are not CLS-
compliant:", nl);
        Show("SByte:    ", w1, w2, w1.CompareTo(w2),
w1.CompareTo((Object)w2));
        Show("UInt16:   ", x1, x2, x1.CompareTo(x2),
x1.CompareTo((Object)x2));
        Show("UInt32:   ", y1, y2, y1.CompareTo(y2),
y1.CompareTo((Object)y2));
        Show("UInt64:   ", z1, z2, z1.CompareTo(z2),
z1.CompareTo((Object)z2));
        }
    catch (Exception e)
        {
        Console.WriteLine(e);
        }
    }

    public static void Show(string caption, Object var1, Object var2,
                            int resultGeneric, int resultNonGeneric)
    {
    string relation;

    Console.Write(caption);
    if (resultGeneric == resultNonGeneric)
        {
        if      (resultGeneric < 0) relation = "less than";
        else if (resultGeneric > 0) relation = "greater than";
        else                        relation = "equal to";
        Console.WriteLine("{0} is {1} {2}", var1, relation, var2);
        }

// The following condition will never occur because the generic and non-
generic
// CompareTo methods are equivalent.

    else
        {
        Console.WriteLine("Generic CompareTo = {0}; non-generic CompareTo
= {1}",
                          resultGeneric, resultNonGeneric);
        }
   }
}
/*
This example produces the following results:

The following is the result of using the generic and non-generic versions
of the
CompareTo method for several base types:
```

```
Boolean:  True is equal to True
Byte:     1 is equal to 1
Int16:    -2 is less than 2
Int32:    3 is equal to 3
Int64:    4 is greater than -4
Decimal:  -5.5 is less than 5.5
Single:   6.6 is equal to 6.6
Double:   7.7 is greater than -7.7
Char:     A is equal to A
String:   abc is equal to abc
DateTime: 12/1/2003 5:37:46 PM is equal to 12/1/2003 5:37:46 PM
TimeSpan: 11.22:33:44 is equal to 11.22:33:44
Version:  1.2.333.4 is less than 2.0
Guid:     ca761232-ed42-11ce-bacd-00aa0057b223 is equal to ca761232-ed42-
11ce-bacd-00
aa0057b223

The following types are not CLS-compliant:
SByte:    8 is equal to 8
UInt16:   9 is equal to 9
UInt32:   10 is equal to 10
UInt64:   11 is equal to 11
*/
```

Remarks

This method implements the System.IComparable<T> interface, and performs slightly better than the CompareTo method because it does not have to unbox the `value` parameter.

The components of `Version` in decreasing order of importance are: major, minor, build, and revision. An unknown component is assumed to be older than any known component. For example:

- Version 1.1 is older than version 1.1.0.
- Version 1.1 is older than version 1.1.1.
- Version 1.1 is older than version 1.1.2.3.
- Version 1.1.2 is older than version 1.1.2.4.
- Version 1.2.5 is newer than version 1.2.3.4.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

CompareTo(Object)

Compares the current Version object to a specified object and returns an indication of their relative values.

C#

```
public int CompareTo (object? version);
```

Parameters

`version` Object

An object to compare, or `null`.

Returns

Int32

A signed integer that indicates the relative values of the two objects, as shown in the following table.

Expand table

Return value	Meaning
Less than zero	The current Version object is a version before `version`.
Zero	The current Version object is the same version as `version`.
Greater than zero	The current Version object is a version subsequent to `version`, or `version` is `null`.

Implements

CompareTo(Object)

Exceptions

ArgumentException

`version` is not of type Version.

Remarks

The components of `Version` in decreasing order of importance are: major, minor, build, and revision. An unknown component is assumed to be older than any known component.

For example:

- Version 1.1 is older than version 1.1.0
- Version 1.1 is older than version 1.1.1
- Version 1.1 is older than version 1.1.2.3
- Version 1.1.2 is older than version 1.1.2.4
- Version 1.2.5 is newer than version 1.2.3.4

Version.Equals Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a value indicating whether two Version object represent the same value.

Overloads

Expand table

Equals(Object)	Returns a value indicating whether the current Version object is equal to a specified object.
Equals(Version)	Returns a value indicating whether the current Version object and a specified Version object represent the same value.

Equals(Object)

Returns a value indicating whether the current Version object is equal to a specified object.

C#

```
public override bool Equals (object? obj);
```

Parameters

obj Object

An object to compare with the current Version object, or `null`.

Returns

Boolean

`true` if the current Version object and `obj` are both Version objects, and every component of the current Version object matches the corresponding component of `obj`; otherwise, `false`.

Version.GetHashCode Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Returns a hash code for the current Version object.

C#

```
public override int GetHashCode ();
```

Returns

Int32

A 32-bit signed integer hash code.

Examples

The following code example demonstrates the Version constructor, and Major, Minor, Build, Revision, MajorRevision, and MinorRevision properties.

C#

```
// This example demonstrates the Version.Revision,
// MajorRevision, and MinorRevision properties.
using System;

class Sample
{
    public static void Main()
    {

    string fmtStd = "Standard version:\n" +
                    "  major.minor.build.revision = {0}.{1}.{2}.{3}";
    string fmtInt = "Interim version:\n" +
                    "  major.minor.build.majRev/minRev = {0}.{1}.{2}.
{3}/{4}";

    Version std = new Version(2, 4, 1128, 2);
    Version interim = new Version(2, 4, 1128, (100 << 16) + 2);
```

```
    Console.WriteLine(fmtStd, std.Major, std.Minor, std.Build,
std.Revision);
    Console.WriteLine(fmtInt, interim.Major, interim.Minor, interim.Build,
                              interim.MajorRevision, interim.MinorRevision);
    }
}
/*
This code example produces the following results:

Standard version:
  major.minor.build.revision = 2.4.1128.2
Interim version:
  major.minor.build.majRev/minRev = 2.4.1128.100/2

*/
```

Version.Parse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

Parse(ReadOnlySpan<Char>)	Converts the specified read-only span of characters that represents a version number to an equivalent Version object.
Parse(String)	Converts the string representation of a version number to an equivalent Version object.

Parse(ReadOnlySpan<Char>)

Converts the specified read-only span of characters that represents a version number to an equivalent Version object.

```
C#

public static Version Parse (ReadOnlySpan<char> input);
```

Parameters

`input` ReadOnlySpan<Char>

A read-only span of characters that contains a version number to convert.

Returns

Version

An object that is equivalent to the version number specified in the `input` parameter.

Exceptions

ArgumentException

`input` has fewer than two or more than four version components.

ArgumentOutOfRangeException

At least one component in `input` is less than zero.

FormatException

At least one component in `input` is not an integer.

OverflowException

At least one component in `input` represents a number that is greater than Int32.MaxValue.

Remarks

The `input` parameter must have the following format:

```
major.minor[.build[.revision]]
```

where `major`, `minor`, `build`, and `revision` are the string representations of the version number's four components: major version number, minor version number, build number, and revision number, respectively. Optional components are shown in square brackets ([and]). The components must appear in the specified order and must be separated by periods.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

Parse(String)

Converts the string representation of a version number to an equivalent Version object.

```
C#
```

```
public static Version Parse (string input);
```

Parameters

`input` String

A string that contains a version number to convert.

Returns

Version

An object that is equivalent to the version number specified in the `input` parameter.

Exceptions

ArgumentNullException

`input` is `null`.

ArgumentException

`input` has fewer than two or more than four version components.

ArgumentOutOfRangeException

At least one component in `input` is less than zero.

FormatException

At least one component in `input` is not an integer.

OverflowException

At least one component in `input` represents a number that is greater than Int32.MaxValue.

Examples

The following example uses the Parse method to parse a number of strings that contain version information.

```
C#

using System;

public class Example
```

```
{
   public static void Main()
   {
      string input = "4.0";
      ParseVersion(input);

      input = "4.0.";
      ParseVersion(input);

      input = "1.1.2";
      ParseVersion(input);

      input = "1.1.2.01702";
      ParseVersion(input);

      input = "1.1.2.0702.119";
      ParseVersion(input);

      input =  "1.3.5.2150000000";
      ParseVersion(input);
   }

   private static void ParseVersion(string input)
   {
      try {
         Version ver = Version.Parse(input);
         Console.WriteLine("Converted '{0} to {1}.", input, ver);
      }
      catch (ArgumentNullException) {
         Console.WriteLine("Error: String to be parsed is null.");
      }
      catch (ArgumentOutOfRangeException) {
         Console.WriteLine("Error: Negative value in '{0}'.", input);
      }
      catch (ArgumentException) {
         Console.WriteLine("Error: Bad number of components in '{0}'.",
                           input);
      }
      catch (FormatException) {
         Console.WriteLine("Error: Non-integer value in '{0}'.", input);
      }
      catch (OverflowException) {
         Console.WriteLine("Error: Number out of range in '{0}'.",
input);
      }
   }
}
// The example displays the following output:
//       Converted '4.0 to 4.0.
//       Error: Non-integer value in '4.0.'.
//       Converted '1.1.2 to 1.1.2.
//       Converted '1.1.2.01702 to 1.1.2.1702.
//       Error: Bad number of components in '1.1.2.0702.119'.
//       Error: Number out of range in '1.3.5.2150000000'.
```

Remarks

The `input` parameter must have the following format:

`major.minor[.build[.revision]]`

where `major`, `minor`, `build`, and `revision` are the string representations of the version number's four components: major version number, minor version number, build number, and revision number, respectively. Optional components are shown in square brackets ([and]). The components must appear in the specified order and must be separated by periods.

> **Important**
>
> Because the string representation of a version number must conform to a recognized pattern, applications should always use exception handling when calling the **Parse** method to parse user input. Alternatively, you can call the **TryParse** method to parse the string representation of a version number and return a value that indicates whether the parse operation succeeded.

The Parse method is a convenience method; it is equivalent to calling the Version(String) constructor.

Version.ToString Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Converts the value of the current Version object to its equivalent String representation.

Overloads

Expand table

ToString()	Converts the value of the current Version object to its equivalent String representation.
ToString(Int32)	Converts the value of the current Version object to its equivalent String representation. A specified count indicates the number of components to return.

ToString()

Converts the value of the current Version object to its equivalent String representation.

C#

```
public override string ToString ();
```

Returns

String

The String representation of the values of the major, minor, build, and revision components of the current Version object, as depicted in the following format. Each component is separated by a period character ('.'). Square brackets ('[' and ']') indicate a component that will not appear in the return value if the component is not defined:

major.minor[.build[.revision]]

For example, if you create a Version object using the constructor `Version(1,1)`, the returned string is "1.1". If you create a Version object using the constructor `Version(1,3,4,2)`, the returned string is "1.3.4.2".

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

ToString(Int32)

Converts the value of the current Version object to its equivalent String representation. A specified count indicates the number of components to return.

C#

```
public string ToString (int fieldCount);
```

Parameters

`fieldCount` Int32

The number of components to return. The `fieldCount` ranges from 0 to 4.

Returns

String

The String representation of the values of the major, minor, build, and revision components of the current Version object, each separated by a period character ('.'). The `fieldCount` parameter determines how many components are returned.

Expand table

fieldCount	Return Value
0	An empty string ("").
1	major
2	major.minor
3	major.minor.build
4	major.minor.build.revision

For example, if you create Version object using the constructor `Version(1,3,5)`, `ToString(2)` returns "1.3" and `ToString(4)` throws an exception.

Exceptions

ArgumentException

`fieldCount` is less than 0, or more than 4.

-or-

`fieldCount` is more than the number of components defined in the current Version object.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryFormat(Span<Char>, Int32, Int32)	Tries to format this version instance into a span of characters.
TryFormat(Span<Byte>, Int32, Int32)	Tries to format this version instance into a span of bytes.
TryFormat(Span<Char>, Int32)	Tries to format this version instance into a span of characters.
TryFormat(Span<Byte>, Int32)	Tries to format this version instance into a span of bytes.

TryFormat(Span<Char>, Int32, Int32)

Tries to format this version instance into a span of characters.

C#

```
public bool TryFormat (Span<char> destination, int fieldCount, out int
charsWritten);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`fieldCount` Int32

The number of components to return. This value ranges from 0 to 4.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryFormat(Span<Byte>, Int32, Int32)

Tries to format this version instance into a span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, int fieldCount, out
int bytesWritten);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of UTF-8 bytes.

`fieldCount` Int32

The number of components to return. This value ranges from 0 to 4.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

TryFormat(Span<Char>, Int32)

Tries to format this version instance into a span of characters.

```
C#

public bool TryFormat (Span<char> destination, out int charsWritten);
```

Parameters

`destination` Span<Char>

The span in which to write this instance's value formatted as a span of characters.

`charsWritten` Int32

When this method returns, contains the number of characters that were written in `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Standard	2.1

TryFormat(Span<Byte>, Int32)

Tries to format this version instance into a span of bytes.

C#

```
public bool TryFormat (Span<byte> utf8Destination, out int bytesWritten);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of UTF-8 bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Applies to

▼ .NET 9 and .NET 8

Product	Versions
.NET	8, 9

Version.TryParse Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Overloads

Expand table

TryParse(String, Version)	Tries to convert the string representation of a version number to an equivalent Version object, and returns a value that indicates whether the conversion succeeded.
TryParse(ReadOnlySpan<Char>, Version)	Tries to convert the specified read-only span of characters representing a version number to an equivalent Version object, and returns a value that indicates whether the conversion succeeded.

TryParse(String, Version)

Tries to convert the string representation of a version number to an equivalent Version object, and returns a value that indicates whether the conversion succeeded.

C#

```
public static bool TryParse (string? input, out Version? result);
```

Parameters

input String

A string that contains a version number to convert.

result Version

When this method returns, contains the Version equivalent of the number that is contained in `input`, if the conversion succeeded. If `input` is `null`, Empty, or if the conversion fails, `result` is `null` when the method returns.

Returns

Boolean

`true` if the `input` parameter was converted successfully; otherwise, `false`.

Examples

The following example uses the TryParse method to parse a number of strings that contain version information.

C#

```
using System;

public class Example
{
   public static void Main()
   {
      string input = "4.0";
      ParseVersion(input);

      input = "4.0.";
      ParseVersion(input);

      input = "1.1.2";
      ParseVersion(input);

      input = "1.1.2.01702";
      ParseVersion(input);

      input = "1.1.2.0702.119";
      ParseVersion(input);

      input =  "1.3.5.2150000000";
      ParseVersion(input);
   }

   private static void ParseVersion(string input)
   {
      Version ver = null;
      if (Version.TryParse(input, out ver))
         Console.WriteLine("Converted '{0} to {1}.", input, ver);
      else
         Console.WriteLine("Unable to determine the version from '{0}'.",
                           input);
   }
}
// The example displays the following output:
//       Converted '4.0 to 4.0.
//       Unable to determine the version from '4.0.'.
//       Converted '1.1.2 to 1.1.2.
```

```
//       Converted '1.1.2.01702 to 1.1.2.1702.
//       Unable to determine the version from '1.1.2.0702.119'.
//       Unable to determine the version from '1.3.5.2150000000'.
```

Remarks

The `TryParse` method is similar to the Parse method, except that it doesn't throw an exception if the conversion fails. Instead, it returns `false` if `input` is `null`, has fewer than two or more than four components, has at least one component that is not an integer, has at least one component that is less than zero, or has at least one component that is greater than Int32.MaxValue.

For the parse operation to succeed, the `input` parameter must be in the following format:

`major.minor[.build[.revision]]`

where `major`, `minor`, `build`, and `revision` are the string representations of the version number's four components: major version number, minor version number, build number, and revision number, respectively. Optional components are shown in square brackets ([and]). The components must appear in order and must be separated by periods.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

TryParse(ReadOnlySpan<Char>, Version)

Tries to convert the specified read-only span of characters representing a version number to an equivalent Version object, and returns a value that indicates whether the conversion succeeded.

```
C#

public static bool TryParse (ReadOnlySpan<char> input, out Version?
result);
```

Parameters

`input` ReadOnlySpan<Char>

A read-only span of characters that contains a version number to convert.

`result` Version

When this method returns, contains the Version equivalent of the number that is contained in `input`, if the conversion succeeded. If `input` is `null`, Empty, or if the conversion fails, `result` is `null` when the method returns.

Returns

Boolean

`true` if the `input` parameter was converted successfully; otherwise, `false`.

Remarks

The `TryParse` method is similar to the Parse method, except that it doesn't throw an exception if the conversion fails. Instead, it returns `false` if `input` is `null`, has fewer than two or more than four components, has at least one component that is not an integer, has at least one component that is less than zero, or has at least one component that is greater than Int32.MaxValue.

For the parse operation to succeed, the `input` parameter must be in the following format:

`major.minor[.build[.revision]]`

where `major`, `minor`, `build`, and `revision` are the string representations of the version number's four components: major version number, minor version number,

build number, and revision number, respectively. Optional components are shown in square brackets ([and]). The components must appear in order and must be separated by periods.

Version.Equality(Version, Version) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified Version objects are equal.

C#

```
public static bool operator == (Version? v1, Version? v2);
```

Parameters

v1 Version

The first Version object.

v2 Version

The second Version object.

Returns

Boolean

`true` if `v1` equals `v2`; otherwise, `false`.

Remarks

The equivalent method for this operator is Version.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

Version.GreaterThan(Version, Version) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the first specified Version object is greater than the second specified Version object.

```
C#
public static bool operator > (Version? v1, Version? v2);
```

Parameters

v1 Version

The first Version object.

v2 Version

The second Version object.

Returns

Boolean

`true` if `v1` is greater than `v2`; otherwise, `false`.

Remarks

The equivalent method for this operator is Version.CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Version.GreaterThanOrEqual(Version, Version) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the first specified Version object is greater than or equal to the second specified Version object.

C#

```
public static bool operator >= (Version? v1, Version? v2);
```

Parameters

v1 Version

The first Version object.

v2 Version

The second Version object.

Returns

Boolean

`true` if `v1` is greater than or equal to `v2`; otherwise, `false`.

Remarks

The equivalent method for this operator is Version.CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Product	Versions
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Version.Inequality(Version, Version) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether two specified Version objects are not equal.

C#

```
public static bool operator != (Version? v1, Version? v2);
```

Parameters

v1 Version

The first Version object.

v2 Version

The second Version object.

Returns

Boolean

`true` if `v1` does not equal `v2`; otherwise, `false`.

Remarks

The equivalent method for this operator is Version.Equals(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version.LessThan(Version, Version) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the first specified Version object is less than the second specified Version object.

```
C#
public static bool operator < (Version? v1, Version? v2);
```

Parameters

v1 Version

The first Version object.

v2 Version

The second Version object.

Returns

Boolean

`true` if `v1` is less than `v2`; otherwise, `false`.

Exceptions

ArgumentNullException

.NET Framework only: `v1` is `null`.

Remarks

The equivalent method for this operator is Version.CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

Version.LessThanOrEqual(Version, Version) Operator

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Determines whether the first specified Version object is less than or equal to the second Version object.

```
C#
public static bool operator <= (Version? v1, Version? v2);
```

Parameters

v1 Version

The first Version object.

v2 Version

The second Version object.

Returns

Boolean

`true` if `v1` is less than or equal to `v2`; otherwise, `false`.

Exceptions

ArgumentNullException

.NET Framework only: `v1` is `null`.

Remarks

The equivalent method for this operator is Version.CompareTo(Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

Version.IFormattable.ToString(String, IFormatProvider) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Formats the value of the current instance using the specified format.

C#

```
string IFormattable.ToString (string format, IFormatProvider
formatProvider);
```

Parameters

`format` String

The format to use. -or- A `null` reference (`Nothing` in Visual Basic) to use the default format defined for the type of the IFormattable implementation.

`formatProvider` IFormatProvider

The provider to use to format the value. -or- A `null` reference (`Nothing` in Visual Basic) to obtain the numeric format information from the current locale setting of the operating system.

Returns

String

The value of the current instance in the specified format.

Implements

ToString(String, IFormatProvider)

Applies to

Product	Versions
.NET	6, 7, 8, 9

Collaborate with us on GitHub

Version.ISpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance into the provided span of characters.

C#

```
bool ISpanFormattable.TryFormat (Span<char> destination, out int
charsWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

destination Span<Char>

The span in which to write this instance's value formatted as a span of characters.

charsWritten Int32

When this method returns, contains the number of characters that were written in `destination`.

format ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `destination`.

provider IFormatProvider

An optional object that supplies culture-specific formatting information for `destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Char>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Version.IUtf8SpanFormattable.TryFormat Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to format the value of the current instance as UTF-8 into the provided span of bytes.

C#

```
bool IUtf8SpanFormattable.TryFormat (Span<byte> utf8Destination, out int
bytesWritten, ReadOnlySpan<char> format, IFormatProvider provider);
```

Parameters

`utf8Destination` Span<Byte>

The span in which to write this instance's value formatted as a span of bytes.

`bytesWritten` Int32

When this method returns, contains the number of bytes that were written in `utf8Destination`.

`format` ReadOnlySpan<Char>

A span containing the characters that represent a standard or custom format string that defines the acceptable format for `utf8Destination`.

`provider` IFormatProvider

An optional object that supplies culture-specific formatting information for `utf8Destination`.

Returns

Boolean

`true` if the formatting was successful; otherwise, `false`.

Implements

TryFormat(Span<Byte>, Int32, ReadOnlySpan<Char>, IFormatProvider)

Applies to

Product	Versions
.NET	8, 9

Void Struct

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Specifies a return value type for a method that does not return a value.

```
C#
public struct Void
```

Inheritance Object → ValueType → Void

Remarks

The Void structure is used in the System.Reflection namespace, but is rarely useful in a typical application. The Void structure has no members other than the ones all types inherit from the Object class.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

WeakReference Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a weak reference, which references an object while still allowing that object to be reclaimed by garbage collection.

C#

```
public class WeakReference : System.Runtime.Serialization.ISerializable
```

Inheritance Object → WeakReference

Implements ISerializable

Examples

The following example demonstrates how you can use weak references to maintain a cache of objects as a resource for an application. The cache is constructed using an IDictionary<TKey,TValue> of WeakReference objects keyed by an index value. The Target property for the WeakReference objects is an object in a byte array that represents data.

The example randomly accesses objects in the cache. If an object is reclaimed for garbage collection, a new data object is regenerated; otherwise, the object is available to access because of the weak reference.

C#

```
using System;
using System.Collections.Generic;

public class Program
{
    public static void Main()
    {
        // Create the cache.
        int cacheSize = 50;
        Random r = new Random();
```

```
        Cache c = new Cache(cacheSize);

        string DataName = "";
        GC.Collect(0);

        // Randomly access objects in the cache.
        for (int i = 0; i < c.Count; i++) {
            int index = r.Next(c.Count);

            // Access the object by getting a property value.
            DataName = c[index].Name;
        }
        // Show results.
        double regenPercent = c.RegenerationCount/(double)c.Count;
        Console.WriteLine($"Cache size: {c.Count}, Regenerated:
{regenPercent:P0}");
    }
}

public class Cache
{
    // Dictionary to contain the cache.
    static Dictionary<int, WeakReference> _cache;

    // Track the number of times an object is regenerated.
    int regenCount = 0;

    public Cache(int count)
    {
        _cache = new Dictionary<int, WeakReference>();

        // Add objects with a short weak reference to the cache.
       for (int i = 0; i < count; i++) {
            _cache.Add(i, new WeakReference(new Data(i), false));
        }
    }

    // Number of items in the cache.
    public int Count
    {
        get {  return _cache.Count; }
    }

    // Number of times an object needs to be regenerated.
    public int RegenerationCount
    {
        get { return regenCount; }
    }

    // Retrieve a data object from the cache.
    public Data this[int index]
    {
        get {
            Data d = _cache[index].Target as Data;
            if (d == null) {
```

```
                // If the object was reclaimed, generate a new one.
                Console.WriteLine("Regenerate object at {0}: Yes", index);
                d = new Data(index);
                _cache[index].Target = d;
                regenCount++;
            }
            else {
                // Object was obtained with the weak reference.
                Console.WriteLine("Regenerate object at {0}: No", index);
            }

            return d;
        }
    }
}

// This class creates byte arrays to simulate data.
public class Data
{
    private byte[] _data;
    private string _name;

    public Data(int size)
    {
        _data = new byte[size * 1024];
        _name = size.ToString();
    }

    // Simple property.
    public string Name
    {
        get { return _name; }
    }
}
// Example of the last lines of the output:
//
// ...
// Regenerate object at 36: Yes
// Regenerate object at 8: Yes
// Regenerate object at 21: Yes
// Regenerate object at 4: Yes
// Regenerate object at 38: No
// Regenerate object at 7: Yes
// Regenerate object at 2: Yes
// Regenerate object at 43: Yes
// Regenerate object at 38: No
// Cache size: 50, Regenerated: 94%
```

Remarks

A weak reference allows the garbage collector to collect an object while still allowing an application to access the object. If you need the object, you can still obtain a strong

reference to it and prevent it from being collected. For more information about how to use short and long weak references, see Weak References.

Constructors

Expand table

WeakReference(Object)	Initializes a new instance of the WeakReference class, referencing the specified object.
WeakReference(Object, Boolean)	Initializes a new instance of the WeakReference class, referencing the specified object and using the specified resurrection tracking.
WeakReference(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the WeakReference class, using deserialized data from the specified serialization and stream objects.

Properties

Expand table

IsAlive	Gets an indication whether the object referenced by the current WeakReference object has been garbage collected.
Target	Gets or sets the object (the target) referenced by the current WeakReference object.
Track Resurrection	Gets an indication whether the object referenced by the current WeakReference object is tracked after it is finalized.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
Finalize()	Discards the reference to the target represented by the current WeakReference object.

GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo object with all the data needed to serialize the current WeakReference object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
ToString()	Returns a string that represents the current object. (Inherited from Object)

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

WeakReference Constructors

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Initializes a new instance of the WeakReference class.

Overloads

Expand table

WeakReference(Object)	Initializes a new instance of the WeakReference class, referencing the specified object.
WeakReference(Object, Boolean)	Initializes a new instance of the WeakReference class, referencing the specified object and using the specified resurrection tracking.
WeakReference(SerializationInfo, StreamingContext)	**Obsolete.** Initializes a new instance of the WeakReference class, using deserialized data from the specified serialization and stream objects.

WeakReference(Object)

Initializes a new instance of the WeakReference class, referencing the specified object.

C#

```
public WeakReference (object? target);
```

Parameters

`target` Object

The object to track or `null`.

Remarks

This constructor creates a short weak reference to `target`.

See also

- Object

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

WeakReference(Object, Boolean)

Initializes a new instance of the WeakReference class, referencing the specified object and using the specified resurrection tracking.

C#

```
public WeakReference (object? target, bool trackResurrection);
```

Parameters

`target` Object

An object to track.

`trackResurrection` Boolean

Indicates when to stop tracking the object. If `true`, the object is tracked after finalization; if `false`, the object is only tracked until finalization.

Examples

The following example creates a cache of data objects with short weak references. This example is part of a larger example provided for the WeakReference class.

```C#
 // Add objects with a short weak reference to the cache.
for (int i = 0; i < count; i++) {
     _cache.Add(i, new WeakReference(new Data(i), false));
 }
```

Remarks

If `trackResurrection` is `false`, a short weak reference is created. If `trackResurrection` is `true`, a long weak reference is created.

UWP	10.0

WeakReference(SerializationInfo, StreamingContext)

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Initializes a new instance of the WeakReference class, using deserialized data from the specified serialization and stream objects.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
protected WeakReference (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

An object that holds all the data needed to serialize or deserialize the current WeakReference object.

`context` StreamingContext

(Reserved) Describes the source and destination of the serialized stream specified by `info`.

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

Remarks

The `context` parameter is reserved, and does not currently participate in this operation.

Applies to

▼ .NET 9 and other versions

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*

WeakReference.IsAlive Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an indication whether the object referenced by the current WeakReference object has been garbage collected.

```
C#
public virtual bool IsAlive { get; }
```

Property Value

Boolean

`true` if the object referenced by the current WeakReference object has not been garbage collected and is still accessible; otherwise, `false`.

Remarks

Because an object could potentially be reclaimed for garbage collection immediately after the IsAlive property returns `true`, using this property is not recommended unless you are testing only for a `false` return value.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

WeakReference.Target Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets or sets the object (the target) referenced by the current WeakReference object.

C#

```
public virtual object? Target { get; set; }
```

Property Value

Object

`null` if the object referenced by the current WeakReference object has been garbage collected; otherwise, a reference to the object referenced by the current WeakReference object.

Exceptions

InvalidOperationException

The reference to the target object is invalid. This exception can be thrown while setting this property if the value is a null reference or if the object has been finalized during the set operation.

Examples

The following example tries to obtain an object from a cache of objects with weak references. If the object was reclaimed for garbage collection, a new object is generated. This example is part of a larger example provided for the WeakReference class.

C#

```
Data d = _cache[index].Target as Data;
if (d == null) {
    // If the object was reclaimed, generate a new one.
    Console.WriteLine("Regenerate object at {0}: Yes", index);
```

```
        d = new Data(index);
        _cache[index].Target = d;
        regenCount++;
    }
    else {
        // Object was obtained with the weak reference.
        Console.WriteLine("Regenerate object at {0}: No", index);
    }

    return d;
```

Remarks

After setting this property to the target object, make sure that there are no other strong references to the object; otherwise, it will not be collected.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9

WeakReference.TrackResurrection Property

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Gets an indication whether the object referenced by the current WeakReference object is tracked after it is finalized.

C#

```
public virtual bool TrackResurrection { get; }
```

Property Value

Boolean

`true` if the object the current WeakReference object refers to is tracked after finalization; or `false` if the object is only tracked until finalization.

Remarks

If `true`, the weak reference is a long weak reference and `true` was specified for the `trackResurrection` parameter in the WeakReference constructor.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

WeakReference.GetObjectData(SerializationInfo, StreamingContext) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo object with all the data needed to serialize the current WeakReference object.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization.
It should not be called or extended by application code.",
DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public virtual void GetObjectData
(System.Runtime.Serialization.SerializationInfo info,
System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

An object that holds all the data needed to serialize or deserialize the current WeakReference object.

`context` StreamingContext

(Reserved) The location where serialized data is stored and retrieved.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

Remarks

This method stores all the information in `info` necessary to serialize the current WeakReference object.

The `context` parameter is reserved and is not currently used in the execution of this method.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	1.1, 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1

WeakReference<T> Class

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Represents a typed weak reference, which references an object while still allowing that object to be reclaimed by garbage collection.

C#

```
public sealed class WeakReference<T> :
System.Runtime.Serialization.ISerializable where T : class
```

Type Parameters

T

The type of the object referenced.

Inheritance Object → WeakReference<T>

Implements ISerializable

Remarks

A weak reference enables the garbage collector to collect an object while still allowing an application to access the object. If you need the object, you can obtain a strong reference to it and prevent it from being collected.

Constructors

Expand table

WeakReference<T>(T)	Initializes a new instance of the WeakReference<T> class that references the specified object.

WeakReference<T>(T, Boolean)	Initializes a new instance of the WeakReference<T> class that references the specified object and uses the specified resurrection tracking.

Methods

Expand table

Equals(Object)	Determines whether the specified object is equal to the current object. (Inherited from Object)
Finalize()	Discards the reference to the target that is represented by the current WeakReference<T> object.
GetHashCode()	Serves as the default hash function. (Inherited from Object)
GetObjectData(SerializationInfo, StreamingContext)	**Obsolete.** Populates a SerializationInfo object with all the data necessary to serialize the current WeakReference<T> object.
GetType()	Gets the Type of the current instance. (Inherited from Object)
MemberwiseClone()	Creates a shallow copy of the current Object. (Inherited from Object)
SetTarget(T)	Sets the target object that is referenced by this WeakReference<T> object.
ToString()	Returns a string that represents the current object. (Inherited from Object)
TryGetTarget(T)	Tries to retrieve the target object that is referenced by the current WeakReference<T> object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

Expand table

WeakReference<T>(T)	Initializes a new instance of the WeakReference<T> class that references the specified object.
WeakReference<T>(T, Boolean)	Initializes a new instance of the WeakReference<T> class that references the specified object and uses the specified resurrection tracking.

WeakReference<T>(T)

Initializes a new instance of the WeakReference<T> class that references the specified object.

C#

```
public WeakReference (T target);
```

Parameters

`target` T

The object to reference, or `null`.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

WeakReference<T>(T, Boolean)

Initializes a new instance of the WeakReference<T> class that references the specified object and uses the specified resurrection tracking.

C#

```
public WeakReference (T target, bool trackResurrection);
```

Parameters

`target` T

The object to reference, or `null`.

`trackResurrection` Boolean

`true` to track the object after finalization; `false` to track the object only until finalization.

Applies to

▼ .NET 9 and other versions

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1

Product	Versions
UWP	10.0

WeakReference<T>.Finalize Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Discards the reference to the target that is represented by the current WeakReference<T> object.

```
C#
~WeakReference ();
```

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6
UWP	10.0

WeakReference<T>.GetObjectData Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

> ⊗ **Caution**
>
> This API supports obsolete formatter-based serialization. It should not be called or extended by application code.

Populates a SerializationInfo object with all the data necessary to serialize the current WeakReference<T> object.

C#

```
[System.Obsolete("This API supports obsolete formatter-based serialization. It should not be called or extended by application code.", DiagnosticId="SYSLIB0051", UrlFormat="https://aka.ms/dotnet-warnings/{0}")]
public void GetObjectData (System.Runtime.Serialization.SerializationInfo info, System.Runtime.Serialization.StreamingContext context);
```

Parameters

`info` SerializationInfo

An object that holds all the data necessary to serialize or deserialize the current WeakReference<T> object.

`context` StreamingContext

The location where serialized data is stored and retrieved.

Implements

GetObjectData(SerializationInfo, StreamingContext)

Attributes ObsoleteAttribute

Exceptions

ArgumentNullException

`info` is `null`.

Applies to

Product	Versions *(Obsolete)*
.NET	Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7 *(8, 9)*
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	2.0, 2.1

WeakReference<T>.SetTarget(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Sets the target object that is referenced by this WeakReference<T> object.

C#

```
public void SetTarget (T target);
```

Parameters

`target` T

The new target object.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0

WeakReference<T>.TryGetTarget(T) Method

Reference

Definition

Namespace: System

Assembly: System.Runtime.dll

Tries to retrieve the target object that is referenced by the current WeakReference<T> object.

```
C#
public bool TryGetTarget (out T target);
```

Parameters

`target` T

When this method returns, contains the target object, if it is available. This parameter is treated as uninitialized.

Returns

Boolean

`true` if the target was retrieved; otherwise, `false`.

Applies to

Product	Versions
.NET	Core 1.0, Core 1.1, Core 2.0, Core 2.1, Core 2.2, Core 3.0, Core 3.1, 5, 6, 7, 8, 9
.NET Framework	4.5, 4.5.1, 4.5.2, 4.6, 4.6.1, 4.6.2, 4.7, 4.7.1, 4.7.2, 4.8, 4.8.1
.NET Standard	1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 2.0, 2.1
UWP	10.0
